Only one observation should be necessary, but it might happen that accidental movement of the subject occurs, in which case there is no reason why further observations should not be made at any stage of the operation, since only a few minutes are necessary for such a proceeding. The use of

the fluorescent screen is essential, so arrangements have been made to enable this to be done in daylight, or bright artificial light, the X ray observer wearing dark glasses for some time beforehand to accustom the eyes to darkness, and an effective fluoroscope being attached. Secondly, the provision of a guide for the operator other than a mark on the skin. It is possible to arrange in connexion with the couch a vertical guide which corresponds exactly with the direction of the radiation. To accomplish this, below the couch in a box (Fig. 1A), which can be moved in any direction freely and easily, we have placed the X ray tube, and springing from this box is a strong and rigid upright (Fig. 1B), to which is attached a cross arm (Fig. 1C) projecting over the couch, all these parts being firmly fixed one to the other, and moving as one piece. At the extremity of the cross arm is attached a small circular fluorescent screen (Fig. 1D), there being provision for lowering or raising the cross arm so that this screen may be

FIG. 3.

Illustrates the fluorescent screen D showing the cross wires to indicate the screen centre, a point corresponding exactly to the centre of the guide which is shown marked F. The special joint N is constructed so that it is impossible that any change of position occurs, both the screen and guide fitting tightly the same socket and locked in position by the pin P. There is a brass collar, O, which is screwed to the arm and is provided for the purpose of easy removal of the screen and guide from the tight-fitting joint. The blunt graduated director is marked B, and the sharp one with its sheath is shown at S S'.

brought in more or less close relationship with the subject lying on the surface of the couch (sliding joint in position shown in Fig. 1E). Since the box and X ray tube are freely movable, and the upright and cross arm are firmly attached to it, the screen will maintain the same relationship to the X ray tube in whatever position it is placed. An X ray tube can be so arranged that only the actual central radiation is used, and under these circumstances the shadow of a foreign body as seen in the screen indicates the exact point in space below which that body lies. In other words, if the X ray tube maintains always the same relationship with the centre of the screen, the central radiation only being used, the shadow of the foreign body seen in the centre of the screen indicates that the body must lie in a line drawn between the tube and the screen centre. In this couch these conditions are easily complied with, for the central radiation is adjusted to correspond with the screen centre, and thus if the shadow of the foreign body is brought central in the screen it must lie below the screen centre in a line between the X ray tube and that point.

The tube box is capable of being firmly fixed in any determined position to the couch by simply pressing a lever, and consequently during observation when the shadow of the foreign body has been arranged in the centre of the screen, the whole—box, tube, upright, and cross arm—can be firmly fixed to the couch by making use of this lever. When this is accomplished the advantage gained is that we have in the screen centre a fixed point below which the foreign body lies. The screen is detachable from the cross arm (at the specially arranged joint seen in Fig. 3N), and in its place can be substituted a sterilisable metal guide carrying a director (seen in Fig. 3F), the point of which is arranged to correspond exactly with the centre of the screen, which has been removed. The guide permits of

movement of the director, only in the direction corresponding to the central radiation—that is, in the line between the screen centre and the X ray tube, which is, in fact, in the vertical plane. If the director running through the guide is advanced through the tissues its point must impinge against the foreign body, for owing to the whole construction being rigid any deflection from the proper plane is impossible. The advantage gained by this procedure is evident, for the surgeon is provided with a director which will unfailingly lead down to the foreign body, permitting him to deal as he pleases with the intervening tissues.

The guide and director are sterilisable, so can be safely handled during the operation. A joint is provided in the cross arm to allow of the director being lifted out of the way and returned in exactly the same position when wanted. (Fig. 4, cross arm lifted out of the way. Fig. 2, returned in identical position—joint at H.) The X ray observer from the moment the observation is made hands over the whole apparatus to the surgeon, and takes away all his part of the construction, so that no unsterilised part is brought near the area of operation.

Two forms of director are provided, one blunt and graduated (Fig. 3B) so that the depth discovered by previous localisation can be made use of, the other sharp in the form of a needle (Fig. 3S) to be introduced in suitable cases into the tissues until the point comes in contact with the foreign body. When using the sharp director a telephone can be attached to announce the contact of the point of director with foreign bodies. The blunt director is provided for use in cases in which it is not advisable to introduce the sharp instrument. For example, in

FIG. 4.

To illustrate the cross arm C raised out of the way at the joint H, the guide F and blunt director B being attached. The arm can be replaced as shown in Fig. 2 without any change in the position of the guide or director.

dealing with the abdomen by using this device it is possible to open the cavity, the guide and cross arm being lifted out of the way to facilitate this part of the operation, retract the parietes, bring the director again into place, and gradually advance its point to the depth previously ascertained, dealing with intervening structures as they present themselves.

It is obvious that before using such an apparatus as I have described an ordinary X ray examination should have been conducted to settle roughly the position of the foreign body and enable the surgeon to decide upon the line of operation, which having been done a surface localisation should be made in order that the depth of the foreign body may be gauged and its position roughly indicated on the skin, to assist in its subsequent observation with the small screen provided in the X ray director.

In conclusion, I wish to express my indebtedness to Dr. W. Lindsay Locke for many valuable suggestions and for the interest he has taken in our endeavour to get the apparatus as mechanically perfect as possible.

Chandos-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

LOSS OF MEMORY DUE TO EXPOSURE.

By H. J. COOPER, M.A., M.B. CANTAB.,
M.R.C.S. ENG., L.R.C.P. LOND.

THE following case seems worthy of record, as apart from the patient being one of the survivors of the ill-fated H.M.S. *Formidable*, it seems that a scientific interest must be attached to the mental condition following the exposure and apparently caused by it, as there was no evidence of injury having been sustained. Similar cases are known to occur after concussion of the brain, but so far as I know none have been recorded as due to exposure.

The patient, a boy aged 18, left the ship in one of the boats about 2 A.M. on Jan. 1st scantily clad, and was exposed to the full force of a very violent southerly gale till 11 P.M. the same day. The boat was constantly swept by the seas and all the occupants were the whole time drenched to the skin, the boat being frequently half full of water and only kept afloat by constant baling. When brought ashore the patient was quite unconscious as were several other occupants of the boat. His pulse was very small and intermittent, and the respirations were very feeble. He could not be made to swallow, so hypodermics of strychnine and brandy were administered; his breathing improved but became rather stertorous. At 4 A.M. on Jan. 2nd he was still very cold in spite of hot water bottles and friction, and the pulse was still very feeble. By 9 A.M. he had recovered consciousness to some extent, but seemed very dazed and passed everything under him in the bed, and this occurred for three or four days. His temperature at 2 A.M. on Jan. 2nd was 100.4° F., and in the evening it was 101°; subsequently it ran a normal course.

By Jan. 9th the patient was up and walking about, but could remember nothing about the incidents in the boat or how he got into it, and

had only a vague recollection of the explosion. At this time he seemed to have no sense of locality and lost his way about the small hospital. He also appeared lethargic, though his companions stated that he was usually of a very lively disposition. On the 12th he was much better and could remember some of the incidents in the boat, such as one of the crew going mad. There was nothing abnormal to be found with the exception of the hands and arms being unusually blue. The pupils were equal and the knee-jerks normal. There was no albumin in the urine.

Though there were six other men who were quite unconscious when landed, some of them, like this patient, not recovering consciousness till many hours after, none of them showed any loss of memory for events which had taken place prior to their becoming unconscious.

Lyme Regis, Dorset.

SPEEDY ENUCLEATION OF THE EYE.

By JOHN FURSE McMILLAN, M.R.C.S. ENG.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS (RET.).

IN these times when celerity is the order of the day it may not be amiss to record a case of enucleation that occurred in practice amongst natives in a clinic at Ferozepoor, the Punjab. The note may be of service having regard to circumstances of war.

The patient was a girl between the age of 5 and 6, suffering from the effects of contagious purulent ophthalmia of the left eye. The patient having been anaesthetised, I affixed the stop-spring speculum and with a hook drew forward and depressed the eyeball, when I was struck by the cramped position of the parts; and so, after having cut round with scissors the conjunctiva above the horizontal equator, I punctured the ball and allowed the vitreous to escape. Then with ease and speed the muscles of the eye were severed; the membranes of the ball were divided at the longitudinal equator, and next carefully trimmed to the eighth of an inch around the optic nerve. There was little or no hæmorrhage. A pad of boracic wool was inserted, and bandage applied. The next morning the wound had almost completely healed by first intention, and at the next visit it was found that the child was so far thought to be completely recovered as to be taken back by her father to her village.

Celerity here was the main point. As regards the danger of sympathetic ophthalmia the risk would appear a minimum, though one would view with caution any tampering with the optic nerve. Let us suppose that the wound does not unite by first intention, as is possible under the conditions of warfare, then it would appear obvious that there is less likelihood of inflammation of the stump than if the optic nerve had been severed. In puncture of the ball the time taken is three and a half minutes; in non-puncture five minutes or over.

ROYAL SANITARY INSTITUTE.—Dr. M. S. Pembrey, lecturer on physiology, Guy's Hospital, and late member of the Advisory Board, Army Medical Service, will open a discussion on Tall *versus* Short Men for the Army, at the Royal Sanitary Institute, 90, Buckingham Palace-road, London, S.W., on Tuesday next, Feb. 9th, at 7.30 P.M. The chair will be taken by Surgeon-General Sir W. Launcelot Gubbins, K.C.B.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF PSYCHIATRY.

The Application of Physiology to the Study of Mind in Health and Disease.

THIS section held its opening meeting of the session on Jan. 26th, Dr. F. W. MOTT, the President, being in the chair.

THE PRESIDENT took for the subject of his address the Application of Physiology to the Study of Mind in Health and Disease, and his theme was the importance of the ductless glands in the human economy, especially their influence upon growth and, later in life, upon reproductive activity and integrity. He quoted with approval Maudsley's contention as to the necessity of attempting the objective method in the study of mind, for, as Maudsley said, that which a just reflection taught incontestably the present state of physiological knowledge illustrated practically; and Maudsley contended 40 years ago that no psychology could endure which was not based upon physiological investigations, though physiology could not expect for many years to furnish the complete data of a positive mental science. Physiology, however, had now made great advances, and in no sphere was this more notable than in the biochemistry of the ductless glands and the influence of their internal secretions on the bodily functions, an addition due, in great measure, to English physiologists. It was very desirable to apply this knowledge to the study of psychiatry. In Maudsley's work on the "Physiology of the Mind" the hormone theory was anticipated, for he said that the overmastering feelings during pregnancy and those arising from puberty could not be explained in consciousness, and that there was reason to believe that each internal organ of the body had its representative control in the supreme cerebral centre. The functional development of the reproductive organs occurring at puberty effected a complete revolution in the mentality of the youth; and he now became susceptible to impressions which were previously a matter of indifference to him; he was now the subject of aimless longings and obscure impulses, and altruistic feelings began to germinate, and he appreciated what others had done for him in the matter of care and nurture. These feelings were not present in cases in which the reproductive organs were removed before puberty. The evolution of the sex glands was also important in regard to disease. Nature was not mindful of the individual, only of the species, and the sexual was the strongest of all the impulses. The desires had their source in the unconscious life. It was a common saying that love was blind, yet it also added a precious seeing power to the eye, which was necessary to materialise the biochemical stimulus and effect the continuation of the species. The language of love was universal; it could not be concealed when it existed, nor feigned where it did not exist. Yet in the present condition of civilisation this was the impulse subjected to the greatest amount of repression. Insanity was especially common at two periods of life: in adolescence and at the involutionary period. He asked whether it should be assumed that the mental disorder of the true insanities or psychoses, even those which terminated in dementia, could be explained by any structural changes in the brain; or should it not rather be believed that they were due to disturbance of the physiological equilibrium and of the internal secretions of the ductless glands, in many instances acting on a weak inheritance? The interstitial gland structure of the sexual organs functioned independently of the genetic gland structure; and functionally correlated with the sexual glands were the thyroid, the parathyroid, the hypophysis, the pineal gland, the cortical portion of the suprarenal gland, the thymus, and probably also the islands of the pancreas. For a proper study of this subject there should be a systematic examination of all these glands in health and disease, at all age periods, and in persons with and without mental disorder. He had obtained objective grounds for the association of aberrant mental conditions with disease of

ductless glands in three cases of myxoedema. In the thyroid gland there was marked increase of lymphoid and fibrous tissue, and a complete absence of colloid material in one, and a great reduction in the others. There was an increase of colloid material in the pars intermedia of the pituitary gland; and the central nervous system showed marked chromolytic changes in the nerve cells, affecting in a grave manner the autonomic bulbar system. There was an association of the myxoedematous syndrome with acute psychosis. During pregnancy the thyroid gland increased in size, and there was a marked colloid increase in the follicles; a similar increase took place during menstruation and at the climacterium. In pregnancy, too, there was an increase in the parathyroids. There was also a large increase in the lipoid cholesterolin content of the adrenal gland, and these cells were, structurally and chemically, closely allied to the cells of the Graafian follicles. The thyroid gland might be of ordinary size yet contain very little gland substance, hence it was necessary to examine microscopically. An interesting case was that of a married woman, aged 57, whose speech was said to have been slow, and who had indistinct tremors of face, hands, and tongue; her memory was impaired, and she had no idea of time or space; she had attempted suicide prior to admission. She became so demented that she was considered to be a case of general paralysis. Post-mortem examination, however, showed that she had not had general paralysis. The sella turcica was very large, the glenoid processes absorbed, the pituitary was twice the normal weight, and the thyroid gland very atrophied and fibrotic. There was an infantile uterus, and the left ovary was destroyed by old salpingitis; the right one was atrophied and damaged. Probably the patient had had gonorrhoea early in life. An increase in the size of the pituitary gland might have an important bearing on the production of mental symptoms; if the cerebro-spinal fluid served as the lymph of the brain, as he believed, excess of the colloid which irrigated the neural spaces might have an important influence on the functions of the organ of mind, but more work was required to remove this from the sphere of imagination. The ovaries of women suffering at an early age from insanity, and dying in early or late adolescence, had been found at the necropsy to be fibrotic. Dr. Laura Forster had made a series of examinations of ovaries in cases of dementia præcox. Those of subjects who had reached the age of 30 showed signs of early involution, and great scarcity of Graafian follicles; also in cases of *manie dépressive* there was a diminution in those follicles. But the value of these findings was greatly lessened by the fact that in a woman who died from heart disease without any mental trouble there was a like reduction. Still, Dr. Forster's work was highly suggestive. With regard to the pineal gland, it had been shown that tumours of the pineal gland occurring in very young people had been associated with precocious development of the sexual functions and the secondary sex characters. It had been thought that the pineal gland might exert some inhibitory function on the development of secondary sex characters. As to the suprarenals, it had been known since the time of Addison that this gland was essential to life. It had been found that the emotion of fear exercised such an effect as to liberate adrenalin in excess into the blood. Elliott had dealt in an illuminating manner with this subject in the Sydney Ringer lectures. The cortical cells of the suprarenal gland were of great importance in the development of the body during its early existence, especially in regard to the brain. And it was of great importance in relation to the development of spermatozoa, and was increased in the pregnant woman; probably the material was necessary for the growing embryo. Adenoma of the cortex of the suprarenal gland had been found associated with precocious sexual development in both males and females. There was also, in the animal series, a correlation between the size of the brain and the amount of adrenal cortex; the cells in its cortex were the source of supply of the lecithin and cholesterolin required for the enormous growth of the cerebral hemispheres in early life. In conclusion, Dr. Mott said that though the subject of biochemistry was still in its infancy, it promised most hopeful results.

Dr. J. G. SOUTAR (Gloucester), in proposing a vote of thanks to the President for his address, pointed out how much the clinical alienist was indebted to those who, like

the President, were working to establish principles on which progress could be made in the treatment of mind disease.

Sir GEORGE SAVAGE seconded, remarking that the President was such a successful pathologist because he did not think the science was to be learned simply from dead matter.

ULSTER MEDICAL SOCIETY.—A meeting of this society was held in the Pathological Laboratory of the Queen's University of Belfast on Jan. 21st, Dr. J. S. Morrow, the President, being in the chair.—Sir John Byers gave an account of a case of severe Pre-eclamptic Toxæmia successfully treated by the Stroganoff method. A very careful chemico-physiological analysis of the urine, made by Dr. John Gibson, was brought forward.—Professor W. St. C. Symmers read a short paper giving an account of the lesions produced in a Soldier's Skull by the Accidental Discharge at Short Range of a Modern Rifle.—Dr. T. S. Kirk read a short note on a case of Fat Embolism following Fracture of the Femur.—Dr. T. Houston read a paper on Bacteriological Diagnosis.—Dr. W. W. D. Thomson read notes on the investigation of a case of Chronic Interstitial Nephritis with an unusual degree of urea retention, and on certain peculiar crystals found in the cerebro-spinal fluid in a case of septic meningitis.—Sir Alexander Dempsey showed a Tumour of the Suprarenal Gland and a Cancer of the Body of the Uterus.—Mr. A. B. Mitchell showed a Carcinoma of the Penis, an Ulcer of the Stomach Resected, and a Gall-bladder containing Gall-stones.—Mr. R. J. Johnstone showed a specimen of Abdominal Pregnancy, a Tumour of the Transverse Colon which gave considerable difficulty in diagnosis, and a very large Fibroid of the Uterus.—Mr. A. Fullerton showed some Renal Calculi.—Mr. Howard Stevenson showed a specimen from a case of Acute Hæmorrhagic Pancreatitis.—Dr. C. G. Lowry showed a Fibrocystic Tumour of the Ovary which caused intraperitoneal hæmorrhage, and a Calcified Tuberculous Pyosalpinx from a woman aged 62.—Dr. G. A. Hicks showed specimens of Tuberculous Fallopian Tubes and a case of Tubal Abortion.—Dr. Thomson showed a Rapid Method of Preparing an Autogenous Acne Bacillus Vaccine, a case of Pseudochyloous Ascites in which Lactescence was due to Globulin, and Blood-films illustrating (1) blood changes in von Jaksch's disease and (2) marked mitotic changes in the megaloblasts in a case of pernicious anemia.—Mr. S. T. Irwin showed a breast with an Adenoma and Multiple Cysts.—Dr. T. S. S. Holmes showed a Kidney with Pyonephrosis.—Specimens were also shown by Professor Symmers and by Sir John Byers.—Full discussions followed the reading of the various papers.

HARVEIAN SOCIETY OF LONDON.—A clinical meeting of this society was held at the Paddington Green Children's Hospital on Jan. 28th, Dr. Edgar G. Bulleid, the President, being in the chair.—The following cases were shown:—Dr. Leonard G. Guthrie: Juvenile Tabes with Optic Atrophy in a boy suffering with congenital syphilis.—Dr. Corry (for Dr. Guthrie): Enlargement of Thyroid Gland in a child aged 6.—Dr. G. A. Sutherland: (1) Tuberculous Peritonitis, showing a very well marked von Pirquet's reaction; and (2) Congenital Pyloric Hypertrophy.—Dr. R. H. Miller: Aortic Regurgitation of recent rheumatic origin in a child.—Dr. W. H. Willcox: (1) Renal Calculus in a man who referred his pain to the side opposite to the kidney in which the stones were shown by X rays to be situated; and (2) Toxic Jaundice, due to poisoning by tetrachloride of ethane, in an employee of an aeroplane factory.—Dr. Frederick Langmead: Muscular Fibrosis in a girl aged 5. Had been under observation since 5 weeks of age for scleroderma, upon which the muscular condition had been superimposed.—Mr. H. W. Perkins showed numerous Pathological and Microscopic Specimens.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 19th, Dr. Arthur Manknell being in the chair.—Dr. William Mitchell gave an X Ray Demonstration, a large variety of plates being shown. Of special interest were a series of plates showing multiple fractures from a case of osteomalacia, and also a series showing the stomach after a bismuth meal in various gastric diseases.—Mr. W. H. Hooton showed a radiograph of both

kidneys in which were huge stones. This case was said to be unique as being the largest bilateral renal calculi on record.—Dr. A. Rabagliati read a paper on the Functions of the Connective Tissue. After minutely describing the anatomy of the connective tissue he laid great stress on the continuity of the areolar tissue throughout the body, and pointed out that this was of great importance in relation to the spread of infections. He then proceeded to elaborate a theory that the connective tissue cells were organs of sensibility inasmuch as they were the organs which received sensations, while the nervous cells and tissues carried out their function of interpreting these sensations.

Reviews and Notices of Books.

Forensic Medicine and Toxicology.

By J. DIXON MANN, M.D. St. And., F.R.C.P. Lond. Fifth edition. Revised and enlarged by WILLIAM A. BREND, M.A. Cantab., M.B., B.Sc. Lond., Barrister-at-Law, Lecturer on Forensic Medicine and Toxicology, Charing Cross Hospital. London: Charles Griffin and Co., Limited. 1914. Pp. 737. Price 18s.

THIS volume is well known, and for advanced students no better text-book can be found. In the present edition Dr. Brend, who is responsible for its production, recognising the thoroughness and accuracy which always characterised the work of the late Professor Dixon Mann, has left the main features of the book as far as possible untouched. By numerous additions he has brought it thoroughly up to date.

An account of the Mental Deficiency Act has been included. The classes of patients who are deemed to be mentally defective within the meaning of the Act are set forth, and the requirements as to the making of orders are explained. A short account is given of the Workmen's Compensation Act, 1906, and some instructive remarks are made on the difficult question of "malingerer." It is pointed out that the real fraudulent malingeringer is relatively rare in comparison with the great number of claims which are preferred under the Workmen's Compensation Act and the National Insurance Act. Dr. Brend recognises four types of cases of fraudulent claim: (1) persons who have no affection or injury of any kind; (2) those who are suffering from lesions deliberately produced; (3) those who represent old-standing disease or injury to be the result of a recent accident; and (4) those who are suffering from the effects of an injury or disease not of a serious character, and who consciously and fraudulently exaggerate their symptoms. We consider this a good practical classification, and medical examiners may simplify their ideas by acting upon it. Many cases of suspected malingering present great difficulties, but the introduction of medical referees has exercised a restraining effect in the prevention of fraudulent claims.

In discussing drugs which have been adopted for the purpose of procuring criminal abortion, attention is rightly drawn to the use of lead, most frequently in the form of pills made from diachylon. The practice appears to have originated in the Potteries, where women working with lead would be likely to discover its effects in this direction. In the part of the book dealing with toxicology an account of the law relating to the sale of poisons has been added, and recent work connected with poisoning by veronal, aspirin, carbon monoxide, lead, ferro-silicin, unsound meat, and other substances has been included.

We have referred to only those portions of the work which have been revised or which are to be found for the first time in this edition. Dr. Brend may be congratulated on the way in which he has modernized this excellent text-book, and we can cordially recommend it both to medical practitioners and students. Barristers also would find it of considerable assistance as a work of reference.

The Blood: A Guide to its Examination and to the Diagnosis and Treatment of its Diseases.

By G. LOVELL GULLAND, M.A., B.Sc., M.D. Edin., F.R.C.P. Edin., Senior Lecturer on Clinical Medicine in the University of Edinburgh, &c.; and ALEXANDER GOODALL, M.D. Edin., F.R.C.P. Edin., Assistant Physician to the Royal Infirmary, &c. Second edition. Edinburgh and London: W. Green and Son. 1914. Pp. 384. Price 15s. net.

WE are glad to welcome a second edition of this book within a relatively short time since its first appearance. Its general scope is not much altered, but it has been brought up to date and has received considerable additions in the process. For the benefit of those who are not already acquainted with the volume we may point out that the first 53 pages are devoted to methods of examination—counting, staining, and so forth; then follows a description of the formed elements of the blood, with their sources and their variations in different animals and different conditions; next comes a detailed account of the various disorders of the blood, or so-called blood diseases; and the remainder of the volume treats of the condition of the blood in other affections and of the parasitic organisms which are found in it.

Among the novel matter appearing in this edition we may mention the discussion of von Schilling-Torgau's views on the structure of the erythrocyte, according to which these cells are supplied with a nucleus, a centriole, and two peculiar intracellular bodies, the glassy body and the capsule corpuscle, giving the red cells a much more complicated constitution than is generally recognised. The authors do not discuss or criticise these views, so that we do not gather how far they accept them. We welcome their plea for the retention of Ehrlich's original classification of cases of leukaemia into lymphatic and medullary, as opposed to complicated subdivision based on special forms of leucocytes found to be present, although mixed forms must be admitted. An appendix is devoted to the question of splenectomy in pernicious anaemia—a procedure which the authors do not regard favourably, as the seat of the trouble is probably in the bone-marrow and not in the spleen. Here as elsewhere the judgment expressed is prudent and commendable.

The book is well got up and well illustrated.

Elements of Pharmacy, Materia Medica, and Therapeutics.

By Sir WILLIAM WHITLA, M.A., M.D., LL.D. Tenth edition. London: Baillière, Tindall, and Cox. 1915. Pp. xii.-680. Price 9s. net.

THE appearance of the tenth edition of a text-book bearing on the title-page the statement that it is the forty-second thousand, would almost warrant a reviewer in considering that no detailed criticism was necessary. In a brief preface, however, the author states that the advent of the new British Pharmacopœia has necessitated changes on every

page, and that the present volume may therefore be regarded as a new book. Those familiar with former editions need feel no alarm at this broad statement. The general arrangement of a wealth of material remains as before; the novelty consists in the assimilation of the changes which must be made if the book is to be brought into harmony with the new standard. The introduction of the metric system is responsible for many of the changes; much space is devoted not only to a reproduction of the tables from the Pharmacopœia, but also to several more detailed tables which will save time and calculation.

As in former editions, the author has shown an admirable discretion in separating from the official monographs just those details which are likely to be of service either to the student or the junior medical practitioner; he omits all reference to standards of purity and to arsenic limits and lead limits. On the other hand, there are many useful hints relating to incompatibility and to convenient methods of securing suitable combinations of new and old remedies. The therapeutic section has been carefully revised, and there is abundant evidence that Sir William Whitla has keenly scanned all recent therapeutic advances. The section on non-official remedies, which extends to over 130 pages, contains information relating to very numerous drugs, nearly all protected by trade names, and in many cases to be regarded as still *sub judice*. In referring to this section, students should note the care with which the author has given the names of those responsible for many of the observations; he does not always indicate that he has himself confirmed the experiences of others.

The prescriptions in the section on therapeutics will serve as good examples to young prescribers, but it may puzzle them to ascertain what system of abbreviation has been adopted. On p. 467, in consecutive lines will be found Tinct. and Tr., and Spirit. and Spt. are of frequent occurrence; nor is there any apparent reason why Syrupi should generally be written in full and sometimes be contracted to Syr. These little inconsistencies do not materially detract from the general high standard of the work for its special purpose. It may be anticipated that it will receive the cordial acceptance accorded to former editions.

The New Parent's Assistant.

By STEPHEN PAGET. London: Smith, Elder, and Co. 1914. Pp. 119. Price 3s. 6d. net.

THE charm of Mr. Stephen Paget's previous essays had led us to regard a new volume of essays by him with the feelings of a schoolboy towards a hamper from home. "The New Parent's Assistant," while consisting like his previous books of a number of individual essays, differs from them in the fact that all the essays have relation to one subject—viz., the bringing up of the child as a sound organism, physically, mentally, morally, and religiously. Mr. Paget's method of assisting the parent differs fundamentally from that of Miss Edgeworth, from whose "Parent's Assistant," needless to say, he has adapted the title. Miss Edgeworth wrote down stories told to occupy the children's attention and so keep them interested while insidiously training them on the moral lines that were the ideal of an age of sentiment. Mr. Paget deems it a more effective method to keep the parents interested while equally insidiously imbuing their

minds with a conception of the change that has taken, and is still taking, place in the old psychological order as it concerns the physical, mental, and moral relations between parents and offspring. While the reader imagines himself as merely being amused, he is, in point of fact, imbibing a wholesome draught of moral values nicely balanced so as imperceptibly to adjust the transition from the placid spirit of the eighteenth and first half of the nineteenth century to that of the adventurous twentieth.

The essays, which are nine in number (and a preface), deal with the self, the development of understanding in the child, true and false authority, understanding in relation to faith, the child's interpretation of nature (which includes a most delicate and tactful handling of the problem of sexual enlightenment), true and false discipline, a homily on the love of London—"for it is not all children who love their London as they ought"—and finally on the use of grandparents. The baby, according to Mr. Paget, is the true fountain of honour, for from the moment of his birth he sets about creating dignities and bestowing titles—"father, mother, uncle, aunt, grandpapa and grandmamma." The concluding essay, entitled "August, 1914," was written after the war began, and in it, with chastened optimism, the author looks forward to the time a few years hence when the darkness of this year shall be transfigured, and the children of his vision shall be "more grave, more patient than we were at their age; quicker to put things eternal before things temporal; more simple in their ways, more moderate in their pleasures, more careful over their words, more willing to look in the face of death, more conscious of God in their daily affairs."

The author's quaint charm of style, his unexpectedness of thought, and his wealth of application of human and scientific lore to the problem of the child, combine to make a fascinating volume.

The House-Fly (Musca Domestica Linn.); Its Structure, Habits, Development, Relation to Disease, and Control.

By G. GORDON HEWITT, D.Sc., F.R.S.C., Dominion Entomologist of Canada. Cambridge University Press. 1914. Pp. 382. Price 15s. net.

THIS book is the successor of one with a nearly identical title by the same author which was published by Sherratt and Hughes for the Manchester University Press, and reviewed in THE LANCET of July 2nd, 1910. It can, however, hardly be called a new edition of that book, as although it still contains the whole of the author's original matter from his monographs published in the *Quarterly Journal of Microscopical Science* in 1907, 1908, and 1909, the great amount of subsequent investigation on the subjects has necessitated the preparation of what is practically a new work; this is suggested by the fact that it contains 193 pages more than the previous book, although its price is 5s. less. It is intended not as a popular work but as a text-book for entomologists, medical men, and health officers. After a brief historical statement the book deals, in six parts, with the structure and habits of the house-fly, the breeding habits, the life-history and structure of the larva, its natural enemies and parasites, other species of flies frequenting houses, the relations of house-flies to disease, and control measures. The diseases discussed in relation to flies are of course typhoid fever and the summer diarrhoea of infants, also anthrax, tuberculosis,

cholera, ophthalmia, plague, small-pox, diphtheria, frambœsia, leprosy, dysentery, syphilis, poliomyelitis, trypanosomiasis, and many others. This part (V.) will be of special interest to medical men and health officers. There are some excellent illustrations, coloured and half-tone, an exhaustive bibliography occupying 36 pages, and an adequate 9-page index. As we commended the previous book, so we commend this.

Manuel de Cystoscopie.

Par E. PAPIN, Chef de Clinique des Voies Urinaires à l'Hôpital Necker. Préface par M. le Professeur F. LEGUEU. Paris: F. Gittler. 1914. Pp. 326. Price 15 francs.

CYSTOSCOPY has assumed such an important part in the diagnosis and treatment of diseases of the bladder and ureters that it is essential that this method of examination should be taught regularly and systematically. In most works on the subject the student is plunged in *medias res*, so that he is confused by being taught too much, but in this book he is introduced step by step into the subject. The instruments employed are described and the mode of using them is carefully explained. The book also contains a description of ureteral catheterisation and pyelography.

The illustrations are very numerous, and we can confidently recommend this work to any student or surgeon who reads French.

A Manual of Diseases of the Eye.

By CHARLES H. MAY, M.D., New York, Chief of the Eye Clinic, Columbia University, New York, 1890-1903, &c., and CLAUD A. WORTH, F.R.C.S. Eng., Surgeon to the Royal London Ophthalmic Hospital. Fourth edition. London: Baillière, Tindall, and Cox. 1913. Pp. 444. Price 10s. 6d. net.

THE fourth edition of this well-known text-book, which differs little, if at all, from the work which is published in America as by Dr May alone, has been revised in detail and brought up to date. There is an excellent chapter on the use of vaccines by Mr. S. H. Browning, which shows most alteration and contains many valuable hints. Reference is made in the preface to the "increased stringency and complexity of the tests required for some of the public services" for colour vision, but the Board of Trade tests for the British Mercantile Marine are quoted from regulations which have been superseded. Mr. C. Devereux Marshall has written a chapter on this subject from the standpoint of Dr. F. W. Edridge-Green's theory, which is accepted now by most ophthalmologists, though it is critically received in some quarters.

Practical Medical Electricity.

By ALFRED C. NORMAN, M.D. Edin. London: The Scientific Press, Limited. 1914. Pp. 226. Price 5s. net.

WITH regard to the title of this book it is open to question if the author has been quite happy in his choice. The student who buys this book with the idea of extending his knowledge of medical electricity proper is likely to be disappointed, since this subject is scarcely touched upon, and such references as there are, are of a very superficial character. The book is really a treatise on the various instruments used in the application of electricity in medicine and surgery; it explains their principle, construction, and mode of application with such clearness and accuracy as to make it evident that the author possesses a knowledge of

the technical side of electricity far in advance of that of the average medical man. In making the above criticism we are not to be understood as implying that there is no place for such a book as this. On the contrary, it fills a real want, and will be of the greatest value to all those who are taking up those branches of medical work where electrical appliances are largely used. To many such the technical and physical problems involved are a serious difficulty from the fact that so few medical students take any interest in electro-physics beyond the minimum required to pass a preliminary examination, and what little they learn they take no pains to remember in after years. They will find, however, in this volume a means by which they can recover many lost opportunities, and for answering the technical and physical questions that are continually suggesting themselves the book will be found most useful. Where explanation offers any difficulty the author has made use of diagrams to make the description more clear, a great improvement on the mere use of an illustration of the finished apparatus from an instrument maker's catalogue, which teaches little or nothing.

The second part of the book is devoted to X ray appliances, including a very useful chapter on the management of the X ray tube, a subject none too well understood by many of the radiographers suddenly called into being by the crisis through which the nation is now passing.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

MEDICATED GELATINE LAMELS.

(MESSRS. SAVORY AND MOORE, LIMITED, 143, NEW BOND-STREET, LONDON, W.)

We referred to this very convenient form of medicament some time ago, but at the present moment its advantages come into special prominence owing to its usefulness in field service. The lamel consists of a thin pliable gelatin sheet about 9 centimetres ($3\frac{1}{2}$ inches) long and 6 centimetres wide, divided into 24 squares. Each square contains a definite dose of medicament. The squares are marked off in grooves so that it is easy to detach one, two, or more, as the circumstances require. The specimens submitted to us included: Dover's powder, 5 grains; extract of cascara sagrada, 2 grains; chlorodyne, 5 minims; strong tincture of ginger, 5 minims; coca extract, $\frac{1}{2}$ grain; tincture of opium, 5 minims; morphine hydrochloride, $\frac{1}{16}$ th grain; Easton's syrup, 30 minims; phenacetin, 3 grains; and quinine sulphate, 2 grains. Out of curiosity as to the accuracy of dosage secured per square, we took 10 squares and estimated in them by analysis the actual amount of quinine. This yielded 1.5 grains of quinine hydrate per square, and as quinine sulphate contains 73 per cent. of quinine hydrate, the amount of quinine sulphate corresponding with this is exactly that stated—viz., 2 grains. The lamels pack quite easily in a small pocket-book, which in its turn is contained in a waterproof case to keep out damp. The complete outfit is very neat and compact, and should be of the greatest service in a campaign.

"SEMPROLIN" LIQUID PARAFFIN PREPARATIONS.

(MESSRS. WILLIAM BROWNING AND CO., 4, LAMBETH PALACE-ROAD, LONDON, S.E.)

We have already reported in these columns upon a series of semprolin preparations, their basis being a highly refined petroleum. We have now received further preparations which have recently been added to the list. The simplest preparation amongst these is a laxative cream which is stated to contain approximately 90 per cent. by volume of liquid paraffin. This figure was confirmed by our analysis, for by extraction of the cream after drying it on the water bath just short of 91 per cent. of petroleum was obtained. This form of petroleum will no doubt appeal to many patients to whom a clear oil is objectionable. The semprolin emulsion with malt contains an active extract of malt associated with petroleum, and we found present 40 per cent. of hydrocarbon. Another semprolin emulsion contains 2 grains of phenolphthalein to each tablespoonful. This particular combination has been used in the treatment of mucous colitis with encouraging results. Lastly, we examined a semprolin emulsion containing 5 grains of salol in each tablespoonful. This intestinal antiseptic is soluble in petroleum, and altogether the combination seems well adapted for the antiseptic treatment of the intestinal contents.

SURGICAL CREOSALGEN.

(MESSRS. C. J. HEWLETT AND SON, LIMITED, 35-42, CHARLOTTE-STREET, LONDON, E.C.)

On examination surgical creosalgen proved to contain just 50 per cent. of active tar acid in a completely soluble form. The clear liquid dissolves in all proportions with water, forming a bright fluid. According to the iodine combination figure of the tar acids creosalgen possesses a higher germicidal value than carbolic acid and probably nearly three times as high. The advantage of this antiseptic for surgical purposes is that in addition to its germicidal efficiency it removes grease and mucus, while it has no corrosive action on surgical instruments.

DIABETIC BISCUITS.

(MESSRS. CALLARD AND CO., 74, REGENT-STREET, LONDON, W.)

These biscuits fulfil a useful purpose in the dietary of the diabetic patient. The carbohydrates, as our analysis showed, are reduced to a minimum. In spite of this they are palatable and attractive. The specimens we received were described as "ponos" biscuits and "ponos" fingers. The analysis of the biscuits was as follows: moisture, 6.70 per cent.; mineral matter, 5.00 per cent.; protein, 61.87 per cent.; fat, 23.80 per cent.; carbohydrates, 2.63 per cent. These preparations enable the physician, when he considers such a course desirable, to give his patient alternately an allowance of carbohydrate in the shape of a standard carbohydrate—e.g., bread—and a diet practically excluding carbohydrate altogether. In this way the carbohydrate toleration of the patient can be followed.

EAU DE COLOGNE, CAERWISC BRAND.

(MESSRS. EVANS, GADD, AND CO., 100, FORE-STREET, EXETER.)

There has long been a formula for eau de Cologne which has been followed in this country. It is a quite good one, and the product is in no sense inferior to the classic one. Eau de Cologne serves a useful purpose in helping to allay congestion of superficial parts, often relieving headache

due to vascular dilatation. This specimen showed an alcoholic strength of 73.93 per cent. by volume. It possesses a fragrant and refreshing odour.

WHATMAN FILTER PAPERS.

(MESSRS. W. AND R. BALSTON, LIMITED, SPRINGFIELD MILL, MAIDSTONE. AGENTS, MESSRS. H. REEVE, ANGEL, AND CO., 15, NEW BRIDGE-STREET, LONDON, E.C.)

Many workers in the scientific laboratory will welcome the introduction of an English manufactured filter paper which gives results equal to those formerly imported from Germany. We have given the Whatman filter paper careful trial and have chosen for the purpose precipitates which are admittedly difficult to collect. Thus precipitations of calcium oxalate, cuprous oxide, and barium sulphate often give difficulty in the filtering process owing to the fineness of the particles, which easily pass through ordinary filtering materials. We found that these filter papers not only gave clear filtrates, but also that they were reasonably rapid in action. Their ash content is low, so that a correction for mineral matter is not necessary in the majority of cases. We found that the total ash obtained on incineration of the paper amounted to 0.121 per 100 parts by weight of the paper. These papers facilitate scientific work and they are an excellent filtering medium; their price is modest.

New Inventions.

A MAXILLARY SPLINT.

THIS is a light wire splint for fractures of the mandible, which maintains the fragments of the fractured bone in immobile apposition, permits movement at the temporo-maxillary joint, and preserves the normal relation of the superior and inferior maxillary bones to one another. (Fig. 1.) The splint is a modification of that of Professor Schröder; it may be adapted to any fracture of the mandible and also of the superior maxilla; moreover, it is of considerable use in cases of partial resection of the former bone and in those of bone transplantation, as it prevents dis-

Fig. 1

placement of the healthy part of the jaw towards the side operated on. (Fig. 2.) In simple fractures accompanied by only slight displacement the splint, then consisting only of wire arch and two clamp bands, can be fitted straightaway in about half an hour, and is worn until the fracture is united. Where one cannot obtain immediate complete reduction, such as in old-standing fractures with displacement, this splint combined with an inclined plane and elastic traction (e.g., rubber band) is of much value. The constant elastic pull gradually reduces the displacement.

The splint consists (1) of two wire arches; (2) four anchor clamp bands; (3) two guiding pins, two shoes (slots), and four tubes, or instead of these an inclined plane; (4) hooks for rubber bands; (5) rubber bands; and (6) ligature wire. The use of the guiding pins and shoes, or the inclined plane, is not restricted to the wire arches alone; they can also be attached to vulcanite or metal splints in case of deficiency of teeth.

The advantages of the splint are the following:—1. It actually maintains the fractured fragments firmly in apposition and permits movement at the temporo-maxillary joint. 2. It can be kept ready in various sizes, thus enabling the surgeon to immobilise any fracture of the jaw straightaway, instead of delaying the treatment. 3. There is no need for a workshop with swaging or casting

Fig. 2

appliances necessary for the making of interdental splints. 4. The patient is able to open and close his mouth 12 to 24 hours after insertion of the splint. 5. The patient does not run the risk of stiffness of the jaw through its being fixed for a long period by an interdental splint. 6. There is no possibility of a bad articulation of teeth through malunion of the fracture, as sometimes occurs with interdental splints which keep the mouth open. 7. The condition of the mouth can be kept constantly under observation, and cleanliness is easily maintained. 8. There is no unsightliness, and discomfort to the patient is the least possible with an intraoral splint.

The splint has been carefully made for me, according to my suggestions, by the Dental Manufacturing Co., Limited, Alston House, Newman-street, London, W.1. C. A. ACHNER, L.D.S. Eng.

LITERARY INTELLIGENCE.—We announced last year a forthcoming book by Sir Clifford Allbutt on "Disease of the Arteries and Angina Pectoris," to be published by Messrs. Macmillan and Co., the work being designed to appear last autumn. The two volumes were practically ready when the war naturally stopped publication. No date has yet been fixed for publication, we understand, but we hope there will be no long delay in a book that will be of great service to clinicians, we feel sure.—Messrs. J. and A. Churchill announce for publication a new (fifth) edition of Sir Henry Morris's "Human Anatomy." Different sizes of type are now employed, to facilitate the work of the student. The letterpress is accompanied by nearly 1200 illustrations, 350 of them being in colours. The same publishers are just issuing a second edition of "Squire's Pocket Companion to the British Pharmacopœia."—Messrs. Smith, Elder, and Co. announce for immediate publication a fifth and enlarged edition of Dr. Ralph W. Leftwich's "Index of Symptoms." The new edition contains a large number of new symptoms and many new tests, while the interlineary notes have been much amplified.—Mr. H. K. Lewis announces for immediate publication the sixteenth edition of the "Extra Pharmacopœia," by W. H. Martindale, F.C.S., and Dr. Wynn Westcott; this edition has been revised with the accustomed thoroughness, and amongst other additions contains a syllabus of the additions, deletions, and alterations in the new British Pharmacopœia. An eleventh edition of Swanzy's "Handbook of Diseases of the Eye" is appearing immediately through the same firm. Owing to the death of Sir Henry Swanzy since the publication of the last edition it has been revised and edited by Dr. Louis Werner, who was associated with the author in the issue of the two previous editions. Mr. Lewis has also in the press a new work on "Occupational Diseases of the Skin," by Dr. R. Prosser White, of Wigan; a translation by Dr. Henry de Meric of Delorme's "Surgery in War"; and a new edition of "Diseases of the Nose and Throat," by Dr. Herbert Tilley. This last work has been largely rewritten and the number of plates and text illustrations increased.

THE LANCET.

LONDON; SATURDAY, FEBRUARY 6, 1915.

The Annual Report of the Medical Officer of the Local Government Board.¹

A NEW annual report of the medical officer of the Local Government Board can always be relied upon to furnish a fund of information on scientific and administrative questions bearing upon the public health, and the volume now issued for 1913-14 is no exception to the rule. The variety of the subjects over which the activity of the central public health department extends is well illustrated by the reports of the medical staff and of the special investigators which Dr. A. NEWSHOLME has selected for publication. Some of these are reports on epidemics which have already appeared separately and been noticed in these columns. Dr. E. P. MANBY'S report on an outbreak of enteric fever in Kenilworth should be a lesson to those responsible for public water-supplies to make frequent surveys of the physical conditions under which the water is obtained, and not to consider that the absence of complaints or a long immunity from water-borne disease signifies that the supply is above suspicion. The report by Dr. F. R. SEYMOUR on lead poisoning at Guisborough brings out the great extent to which lesser degrees of ill-health may be found in a community dependent on a water-supply which is capable of acting on lead pipes; while Dr. H. A. MACEWEN gives an interesting account of an outbreak in South London of diphtheria which was due to milk obtained from a farm where diphtheria infection was present both on the teats of the cows and on the hands of certain of the milkers. Dr. MACEWEN also contributes to this volume the history of an outbreak of small-pox in a cotton mill at Milnrow, in Lancashire, in which infection seems clearly to have been introduced by imported raw cotton, apparently that coming from Mexico. Summaries are given of the reports of different inspectors in the medical department on the sanitary circumstances of about 50 administrative districts in England and Wales. If these are representative it must be concluded that much has still to be done by many local authorities in the appointment of a sufficient sanitary staff, the provision of isolation hospitals, attention to unhealthy conditions of housing, doubtful water-supplies, absence of sewerage, and other matters. The summaries of the sanitary conditions in Llanelly, Lley, and Aberayron suggest

that many Welsh districts in particular need strong central pressure to secure some elementary sanitary improvements which have long been effected in other parts of the country which are not usually regarded as specially progressive.

The Local Government Board has recently shown much activity in inducing local authorities to take those measures for the care and supervision of pregnant women, infants, and children under school age which are now generally grouped under the term "maternity and child-welfare work." In this organisation the woman health visitor plays an important part, and the prospects which these posts offer to educated women who desire to do good social service and are not afraid of hard work deserve to be better appreciated than they are at present. The report contains a memorandum on health visiting by Dr. J. E. LANE-CLAYPON, which deserves special attention in this connexion. Dr. LANE-CLAYPON insists that the value of the health visitor can be enormously increased if she is able to begin her work, not after the notification of a birth, but during the period of pregnancy, acting as part of the staff of a local maternity centre or clinic to which expectant mothers are encouraged to come, at any stage before their confinement, for treatment, advice, or supervision in health matters. The development of local maternity centres, health visiting, and similar undertakings for child welfare is now, we know, being facilitated by a scheme of Government grants, and Dr. NEWSHOLME'S observations on the scope and value of this work will be welcomed by medical officers of health and others who are endeavouring to secure local progress in these directions. The reports of research work carried out for the department are fewer than usual, but Dr. F. W. ANDREWES'S investigations of the causes and conditions associated with arterial degeneration are continued, and reports are issued by Dr. F. R. BLAXALL on chemical substances which can be used to supplement or replace glycerine as a means of quickly freeing vaccine lymph from extraneous organisms without prejudicially affecting its potency. Specially good results have been obtained by the use of oil of cloves in the preparation of glycerinated lymph. Foreign intelligence work in regard to exotic diseases has always formed an important part of the duties of the medical department of the Local Government Board, and we miss from the present volume the yearly account of the world prevalence of cholera, plague, and yellow fever which has long been a feature of the series. The account for 1913-14 is, however, to be issued as a separate publication. Other sections of the volume deal with the work of the inspectors of foods, and with the seasonal and local prevalence of cerebro-spinal fever and poliomyelitis.

The progress of the national measures for combating tuberculosis naturally receives much prominence in Dr. NEWSHOLME'S report. In 1912-13 the Local Government Board completed its programme

¹ Supplement to the Forty-third Annual Report of the Local Government Board. Cl. 7612. London: Wyman and Sons, Fetter-lane; Edinburgh: H. M. Stationery Office; Dublin: E. Ponsonby; Abroad: T. Fisher Unwin. Price 1s. 11d.

for notification of tuberculosis by an Order making all forms of the disease notifiable. The provisions of the National Insurance Act, 1911, as to sanatorium benefit came into operation, the capital grant under the Finance Act, 1911, of one and a half millions for the provision of institutions for the treatment of tuberculosis in the United Kingdom became available, and the Treasury decided to defray one-half of the cost of approved schemes of local authorities for the treatment of tuberculosis in so far as this was not already covered by contributions from insurance funds. During the year which followed all these measures have had to be put into working order by active organisation on the part of the central department, and very effective progress has now been made. By July, 1914, 37 out of 50 county councils and 53 out of 76 county boroughs had received official approval to what are termed "fairly complete" schemes, while others had their proposals under consideration. Only a small minority proposed schemes which were "partial" or limited to the provision of dispensaries. By the same date nearly 200 clinical tuberculosis officers had been appointed, while in nearly all cases the medical officer of health of the county borough or administrative county was appointed administrative tuberculosis officer. Dispensaries have multiplied, and much attention has been given to the provision of sanatorium and hospital accommodation for tuberculous cases. Reckoning sites for new sanatoriums and hospitals already approved, institutional provision will shortly be available for all classes of tuberculous cases at the rate of one bed for every 2557 persons in England. The provision of beds is likely to increase further, and if county boroughs generally follow the lead of Bradford and Sheffield, something like one bed per 1200 of population is likely to be needed to meet the current requirements of pulmonary tuberculosis alone. Provision of dispensaries and beds is, however, only a part of the problem if tuberculosis is to be dealt with systematically on the lines advocated by the Government departments. Success on these lines must depend on the solution of the large number of practical questions which arise in the actual working of a somewhat complicated machinery, and the medical officers and inspectors of the Local Government Board have been indefatigable in giving attention to these working details and in facilitating local arrangements. Dr. NEWSHOLME embodies some of the results in the present report, which contains observations on the classification of cases, the relation of tuberculosis officers to district medical officers of health, the duration of institutional treatment, and many other matters which will be carefully studied by those concerned with this branch of public hygiene. Reference should also be made to a useful memorandum prepared by Mr. J. E. CHAPMAN on "observation beds," based on experience at Sheffield, which sets out the advantages of attaching such

beds to tuberculosis dispensaries and placing them under the control of the dispensary medical officer for clinical observation. It seems clear that this arrangement may often prevent unprofitable demands on residential institutions.

For statistics of tuberculosis Dr. NEWSHOLME necessarily depends mainly on death-rates. Notification of new cases cannot yet be said to make a reliable basis for comparison of the prevalence of the disease either in one year with another or in one district with another district. The figures frequently show that counties and boroughs which are high on the list as regards tuberculosis notifications are low in respect of tuberculosis deaths, and *vice versa*. On the massed figures for all counties, all county boroughs, and all metropolitan boroughs there are at present for pulmonary tuberculosis from 2'0 to 2'5 notifications for every male death, and from 2'1 to 3'4 for every female death; for other tuberculosis the proportion lies between 2'8 and 4'4 notifications to each death, and Dr. NEWSHOLME considers that special inquiry into the completeness of notification is desirable in any district where the notifications of phthisis do not number more than twice the deaths from the disease. In statistical as well as in clinical matters much depends on the extent to which bacteriological aids are used in diagnosis. The report, to which we shall return in more detail in an early issue, records a considerable increase in the arrangements of local authorities for the examination of sputa, while on many other grounds Dr. NEWSHOLME lays stress on the importance of pathological laboratories being established or further developed under the auspices of county councils or municipalities.

Civilian Service and Military Claims.

THE most ardent advocate of conscription recognises that the training of the male population for complete readiness to serve their country as soldiers does not imply that they will all be serving at the same time if war should break out. In actual time of war only a certain proportion of the population can be with the colours. It is all to the good that military training should be widespread, and that material for the regiments should be recruited in a more or less trained condition; but civilian business of the country must be carried on, even with increased activity in many directions, and for this a large body of men is required. A great deal of military work, strictly military work, must be done by people who remain at home, and while some businesses will inevitably decline during war, the ordinary wants of the population at such a time are modified, not abolished. This country, for example, cannot raise, equip, and feed an army of a million without employing many thousands of people in more or less special capacities, while the bulk of the population still remain with their usual, or more than their

usual, demands to be met. In these circumstances the question is constantly arising whether in an individual instance the duty of a citizen is to continue to discharge his civilian service or to respond to the trumpet's call. In the profession of medicine and in that of education many difficult cases have presented themselves, and on looking into them it becomes clear that the decision, though regulated by the general conditions of the country, cannot be made in any general manner. There will be no universal rule that those discharging certain civilian duties are right to leave them, and that those discharging other civilian duties will be right to continue them. Every case must be thought out carefully and the decision come to with a due regard for the welfare of the people. The defence of the country by sea and land will always come first, but it must be that the cause of defence is aptly served by much civilian work. The question can never arise whether it is patriotic of, say, the official of a large railway, who has successfully been responsible for the safe conduct of hundreds of troops, and is wanted to carry on his experienced work, to take a commission as a lieutenant for the good of his country in circumstances where his special knowledge cannot be brought to bear. Here the question does not arise, because we can all see that it is for the good of his country that he should help in our defence by expediting our military movements. But there is no such clear-cut opinion to be given in the case of many other civilian occupations not so closely allied to military service, and the position of the medical officer of health or the educational medical officer is one where real difficulty arises, and where both tact and forbearance should be exercised in coming to a judgment.

The following case has struck us as admirably illustrative. The medical officer of health of the borough of Battersea has been gazetted a lieutenant in the 2nd London Sanitary Company (R.A.M.C., Territorial Force), and it may be added that in these columns we have regularly announced in an inviting manner to our readers similar opportunities. The Finance Committee of the Battersea Borough Council having recommended to the Council that their officer should be allowed the difference between his salary and his service pay and allowances during absence, the chairman of the committee, though he formally moved the adoption of this course, as a councillor spoke against it. Various councillors maintained that the work of safeguarding the health of a populous district at home was as patriotic an action as performing sanitary duties with the army, while in consequence of the growing shortage of medical men it was apprehended that there would be considerable difficulty in obtaining someone to take the vacant place. On the other side, speakers maintained that, when the country called, local matters must be disregarded and all interests sacrificed to those of the empire. These councillors

considered that their medical officer had shown true patriotism in exchanging for a subordinate military appointment with its arduous work and probable risks the safety and comfort of home, and they held that if the Council sought to restrain him from taking the commission they would expose themselves to ridicule, and if they treated him ungenerously they would incur public odium. It appeared also that the Council had passed a resolution encouraging their officers and employees to undertake military service and guaranteeing to bring their pay up to their customary salary, but it must be admitted that this resolution, though drawn up in inclusive terms, was not intended to apply to chief officers. That the Battersea councillors perceived the difficulty was shown by the fact that the voting was very close. At first the recommendation of the Finance Committee was declined by one vote, but on a division being taken the odd vote was given on the other side. A proposal to refer the matter back to the Finance Committee was lost, and the Council, by a very narrow majority, decided that the military pay of the medical officer of health should be made up to his official salary during his absence. The difficulty of deciding where the right lies in these cases is thus proved by the course of the voting at Battersea. A somewhat similar position arose at the same time at Wolverhampton, where the civilian authority took a different view with respect to their educational medical officer. At the last monthly meeting of the Wolverhampton Education Committee consideration was given to an application made by the school medical officer of Wolverhampton for leave of absence during the duration of the war that he might accept a commission in the medical department of His Majesty's forces. The committee decided that in the event of the officer accepting a commission it would be impossible satisfactorily to proceed with the school medical service under the advice of a temporary substitute, and that if the commission were accepted by the medical officer steps would have to be taken to appoint a permanent successor. The Education Committee added that if urgent need for their medical officer's services should later arise they would, of course, be willing to let him go.

The different decisions come to by equally responsible and patriotic bodies with regard to the acceptance by their senior administrative officers of commissions, together with the extreme difficulty shown by one of these bodies in coming to a conclusion, sufficiently show that there can be no general rule. The public health of the country and the maintenance of a State scheme of education upon sound sanitary lines are matters of the first importance to all. That our civilian population should not become a burden upon the public purse through sickness, and that our rising generation should be free from disease, comprise the very welfare of the nation, and it must not be lightly jeopardised; our army and navy are fighting for our existence, it is due to them

to see that we maintain an existence worth fighting for. The fighting services have the first claim on all who can serve, but the authorities who are responsible for the health and education of the public deserve to be treated with every consideration by their principal administrators. The longest possible notice should be given to them by such administrators before leave of absence is sought, and it is getting clear that the difficulty of providing substitutes must be taken into consideration. There may soon be a real shortage of medical men. We place the military exigencies first, but all care should be taken that this shortage does not occur in important administrative posts.

Annotations.

"Ne quid nimis."

THE CARE OF THOSE BLINDED IN WAR.

It is probable that of all the accidental disabilities that can befall a person in the vigour of life none is more distressing or more wholly arouses the pity of all kindly disposed persons than that of complete traumatic blindness. Plunged suddenly into a world of unaccustomed darkness without warning or time gradually to accustom himself to his changed conditions, and gradually to develop compensating methods of intelligence, his lot is terrible indeed. We understand that 22 such sufferers, including two officers and one non-commissioned officer, have up to now been returned from the front. The chances of such an accident happening are, in view of the greater dispersiveness of modern missiles, probably considerably greater than in former wars, and it behoves the country not only to make adequate provision for the skilled care of such patients in the early stages of their injury, so that whatever amelioration of the evil effects is possible may be secured before it is too late, but also to recognise the peculiarly disabling effect of such injuries and to plan for an adequate scheme of compensation. The first object has already been taken up, as was indicated in our "War" column last week, and all soldiers blinded at the front are to be sent straight to the 2nd London General Hospital at Chelsea, where provision is being made for them to receive the best of skilled attendance, so that all that can be done shall be done to mitigate the result. With regard to the second point, Mr. C. Arthur Pearson, President of the National Institute for the Blind, enters a most earnest plea in a letter to the *Morning Post*. He calls attention to the pressing need for special consideration as regards the question of adequate pensions and allowances, for, as he rightly points out, there are many directions in which a blind person has to bear expenses not imposed on those who can see—e.g., the necessity for a guide, which doubles the expenses of travelling. We trust that systematic efforts will be made to deal in a generous spirit with this large subject.

A NEW DISEASE OF RODENTS TRANSMISSIBLE TO MAN.

ABOUT three years ago, when Dr. G. W. McCoy, of the United States Public Health Service, was investigating the distribution of plague among the hordes of ground squirrels which infest many parts of the State of California, he discovered among them what appeared to be a new disease. In conjunction with Dr. Charles W. Chapin he subsequently made a series of experiments on these rodents, as well as on guinea-pigs, white rats, and grey mice, and found that while the lesions caused by the new malady resembled those of plague, further examination demonstrated that the disease was due to a specific organism to which the name of *Bacterium tularense* was given. Later it was shown that monkeys were also susceptible to this infection, and it was in consequence expected that the disease would be found in man. In a recent communication published in our American contemporary, *Public Health Reports* for Dec. 18th last, Professor W. B. Wherry, of the University of Cincinnati, describes two human instances of this new malady, in which the chief symptoms were acute ulcerative conjunctivitis with enlargement of the preauricular and cervical glands, fever, and marked prostration. The first patient was a man employed as a meat cutter in a cheap restaurant, the second being a farmer's wife. In searching for the source of infection in these human cases Professor Wherry's suspicion fell on ground game, and shortly afterwards it came to his knowledge that wild rabbits were dying in large numbers in Kentucky and Indiana. He procured two of these dead rabbits for examination, and both of them showed the gross lesions caused by *B. tularense*. Inoculation experiments on laboratory animals conclusively confirmed the diagnosis. One of the above-mentioned patients lived about six miles from the spot where the two dead rabbits were picked up. Professor Wherry believes that this new disease of rodents may be widely distributed and that extensive epizootics may occur with comparative frequency. Both of the persons who were attacked admitted that they had lately been cutting up wild rabbits in preparation for cooking; it is thought probable that they conveyed the virus by unwashed hands. On the basis of animal experiments it is regarded as possible that ulcerative rhinitis, ulcerative or membranous sore throat, gastro-intestinal infection or lymphadenitis, secondary to the skin affection, may also occur as results of the infective process. Susceptible rodents can be infected by feeding or by the introduction of infective material into the eye or nose, or through an abrasion of the skin. McCoy and Chapin, while searching for a mode of transmission of the disease among ground squirrels, succeeded on two occasions in conveying the malady by means of squirrel fleas. Assistant Surgeon N. E. Wayson, of the United States Public Health Service, has published a paper in which he describes the possibility of experimentally transferring *B. tularense* from infected material to healthy rodents through the agency of stable-flies and also common house-flies. Whether this mode of transmission occurs in nature is not yet proved, but Dr. Wayson is continuing his investigations. As regards prophylaxis, Professor Wherry thinks it advisable to warn all persons who in the course of their duties have to cut up or handle wild rabbits to wash and scrub their hands very carefully

after touching the animals, so as to prevent the transference of the virus to the eyes or other parts of the body where *B. tularensis* might find a point at which to effect an entrance into the human system.

THE TREATMENT OF WOUNDS IN WAR.

It is very important that we should not fail to recognise that in new conditions new forms of treatment may be needed. In the present war the conditions are in many respects very different from those met with in civil life, and even from those encountered in previous wars; therefore it is necessary that surgeons should have an open mind to consider without prejudice any new method of treatment which may be brought forward. In the present number of THE LANCET we publish a method of treatment of contused and lacerated wounds which Dr. Louis Menci re has employed widely during the present war, and with which he has achieved no small measure of success. It consists essentially in a very free use of antiseptics in the wound, preference being given to the successive application of perchloride of mercury, carbolic acid, and peroxide of hydrogen. This treatment is followed by the daily use of an antiseptic lotion, which he claims destroys septic organisms while not interfering in any way with the life of the cells of the tissues. Dr. Menci re gives a full account of the mode of application of his method in his paper, and to that we refer the reader for fuller particulars.

PITUITRIN IN ACUTE HEART FAILURE.

THE marked action of pituitrin on unstriated and striated muscular fibre, and especially its action on the uterus, has led Professor Zueblin, of the University of Maryland, to use the drug in a condition for which it does not appear to have previously been recommended—failing heart when there is demanded an immediate effect which cannot be obtained from the usual cardiac remedies (digitalis, strophanthus, &c.). In the *Boston Medical and Surgical Journal* of Dec. 24th, 1914, he has reported a series of seven cases thus treated, of which the following are examples. A poorly nourished man, aged 33 years, was suffering from syphilis, nephritis, and acute dilatation of the heart. The pr cordial region was bulging and the apex beat was in the seventh interspace in the anterior axillary line. Cardiac dulness extended 5½ inches to the left and 3 inches to the right of the mid-sternal line. A double blowing murmur was heard in the mitral and tricuspid areas. The second pulmonic sound was accentuated. The pulse was 115. One cubic centimetre of pituitrin was injected subcutaneously. On the following day the apex beat was inside the anterior axillary line and cardiac dulness extended to the right sternal border. The pulse was 95 and the patient felt more comfortable and showed marked improvement. A course of digitalis was then given and he gradually improved. The reduction of the cardiac dulness under the pituitrin was remarkable; the transverse diameter diminished 2½ to 3 inches in the 24 hours. In another case a carpenter, aged 66 years, was suffering from aortic stenosis. The pr cordium bulged; the apex beat was in the sixth intercostal space outside the nipple line. Cardiac dulness extended 5½ inches to the left of the mid-sternal line and 2½ inches to the right. One cubic centimetre of pituitrin was given. On the following

day cardiac dulness extended 4½ inches to the left and ½ inch to the right of the midsternal line. The pulse, which previously was 78, had fallen to 70. The transverse diameter of the cardiac dulness was reduced by 3 inches. In a third case a man, aged 60 years, was suffering from chronic myocarditis, general arteriosclerosis, chronic nephritis, and anasarca. The heart was so dilated that dulness extended 5½ inches to the left and 3½ inches to the right of the midsternal line. There was a double murmur over the mitral and tricuspid areas, with an accentuated second pulmonic sound. Under digitalis and strophanthus he did not improve. There was fluid in the left pleural cavity reaching as high as the fourth interspace. The patient was dyspno ic, restless, and cyanotic. The pulse was 110, irregular, and compressible. There were albumin and granular casts in the urine. Pituitrin was given, and 24 hours later cardiac dulness extended 4½ inches to the left and 1½ inches to the right of the midsternal line, and the pulse was 80. However, death took place two days later. Notwithstanding advanced disease the diameter of the cardiac dulness was reduced 2½ inches in the 24 hours. Professor Zueblin's cases are suggestive, but not numerous enough for generalisation. It must also be borne in mind that several writers consider heart disease, arteriosclerosis, and kidney disease contra-indications to the use of pituitrin. It may be remembered that obstetricians have also issued warnings against indiscriminate use of the drug. In the case of arterial disease in the aged a sudden increase of blood pressure produced by pituitrin might cause apoplexy. Under such conditions the drug should therefore be given with caution.

CEREBELLAR SYMPTOMS AND LOCALISATION.

As has not infrequently been the case in the history of medicine, the functions of an organ may appear to be established so satisfactorily by experimental and clinical evidence that under the influence of teaching and text-book description they become "classical." Then in turn the "classical" view is questioned, and after a longer or a shorter period the older terminology disappears as fresh data result in the adoption of an entirely new method of envisaging the clinical facts, which evidently have not themselves changed. Our knowledge of the functions of the cerebellum has been passing through such a transformation. The student has been taught that the "classical" symptoms of cerebellar disease are a swaying, staggering gait, forced movements—"lurching" in one direction or another—ataxia of the limbs, nystagmus, and vertigo. But gradually research has commenced to dismember this cerebellar complex. It is tolerably clear that nystagmus and vertigo are due to concomitant disturbance of the vestibular apparatus at least as much as to implication of the cerebellum itself, if not indeed really independent of cerebellar activity. The familiar ataxia is now known to be a symptom-complex rather than a pure symptom, and its place is being taken by a newer conception, asynergy. In an interesting review of the present situation as regards cerebellar disease in the *Journal of the American Medical Association*, Dr. C. K. Mills and Dr. T. H. Weisenburg, of Philadelphia, define synergy as the power or faculty by which movements more or less complex, but functionally definite, are associated in a special act or acts. In a broad sense it is motor association, this

association being carried out in movements of different parts of the same limb or in synchronous movements of the trunk and limbs, or of the head, trunk, and limbs. When it is defective from cerebellar disease, motor adjustments are mis-measured, and the result is termed dysmetria. This is the expression which is now replacing ataxia. Analysis of the defective movements of the cerebellar patient has been rendered more exact by recourse to the kinematograph. In this way the components of the defective movements are readily traceable, and the contention of the more recent investigators of cerebellar function has been corroborated that the underlying basis of cerebellar symptomatology is asynergy revealing itself in dysmetria. The physician should note, further, that defect in motor adjustments is discoverable not merely in the cerebellar patient's gait, but also in the use of his limbs, unilaterally or otherwise, or in segments of the limbs, as well as in speaking, eating, and in much else that is done by him. This leads in its turn to a further modern conception of great importance—viz., the possibility of localisation in the cerebellum. By means of the kinematograph Dr. Mills and Dr. Weisenburg have shown that asynergy may be confined to the pelvic girdle or to the shoulder girdle, the gait being different in the two cases, though equally cerebellar. They have analysed cases, familiar enough to the neurologist, in which the dysmetria was confined to one limb. They have recorded a case of hæmorrhage into the antero-superior portion of the cerebellum in which the patient showed exquisite asynergy in his tongue, facial and laryngeal movements only. Mastication and deglutition were almost impossible because of the asynergy of the involved musculature. It is true that more research, clinical and pathological, is requisite ere a map of localised cerebellar function can be made out, but the evidence at present available indicates that on the superior surface of the cerebellum the head and eyes, face, jaws, tongue, larynx, pharynx, neck, and trunk are represented more or less in the middle line, and posteriorly round to the inferior surface in the middle line (vermis). On the superior surface, laterally, is the focus for the upper extremity, right and left respectively, with abduction, adduction, extension, and flexion separable. On the under surface is the centre for the lower extremity, in an analogous fashion. It is desirable to recognise that this cerebellar "localisation" is not so precise as cerebral localisation. There is not likely to be an exclusive localisation for a limb or segment of a limb in the cerebellar cortex. Synergic activity of the musculature of the body is so complex that cerebellar localisation must be compound, as it were. But the authors insist with reason that a composite has always within it factors or elements which can to a greater or less extent be separated from the entire mass. The practical significance of recent work on the cerebellum and its activities is that diagnosis becomes distinctly more exact.

VAGOTROPISM IN INFLUENZAL INFECTION.

E. Paganelli has recently drawn attention in *Il Morgagni* to the fact that the Stokes-Adams syndrome is occasionally met with in an acute form during an attack of influenza, and has shown in four patients that bradycardia and neurocentral phenomena peculiar to the Stokes-Adams syndrome, such as syncopal and vertiginous attacks with vomiting, may occur

as a special characteristic in some epidemics of this disease. The author's cases afford evidence that bradycardia and the rest of the syndrome may be considered due to an affinity of the toxin towards the vagus without the occurrence of myocardiac lesions or lesions of the nervous centres. The characteristics of the condition were sudden onset, marked instability of the bradycardia and its modification by the action of belladonna and atropine, a cardio-systolic arterial pressure raised in comparison with a co-existing arterial hypotonia, and a more or less rapid recovery. The attacks were of variable duration from a few to several hours, and repeated in some of the patients at intervals of some hours or even of days. The clinical picture was one of gravity, yet in the epidemic of influenza referred to by the author the condition was met with only in four instances out of 40 cases during two months, nor was the course of the disease appreciably aggravated by the occurrence of such acute symptoms.

SELF-REGULATION OF THE GASTRIC ACIDITY.

For a considerable time in medical science it has been the established conviction that the acidity of the gastric juice—i.e., the quantity of free hydrochloric acid in man and animals—usually varies from 0.1 to 0.2 per cent. This figure was arrived at by examining the stomach contents but not the pure juice. It was, however, astonishing to find that in the dog's stomach, an isolated portion, the acidity was as high as 0.5 to 0.6 HCl; the same applied to rabbits and cats. Later the pure juice of the stomach was obtained in human beings, and in them also the acidity was from 0.32 to 0.47 per cent. The acidity is also constant. Clinicians, however, still accepted this as definite hyperacidity. And this because no one could explain why the gastric juice from the whole normal stomach as distinguished from isolated portions should almost always contain a lower concentration of acid. The answer now is that the acidity of different acid fluids introduced into the stomach is reduced during their stay in that organ; the reduction of acidity applies also to its own acid juice. How is such reduction effected? Professor Boldyreff, in the *Quarterly Journal of Experimental Physiology* (1914, vol. viii., p. 1), quotes some conclusive experiments to show that such reduction is effected by the alkaline pancreatic juice which regurgitates into the stomach, such action being itself initiated by the acidity. The experiments were performed on dogs. Ligature of the pancreatic ducts results in a definite delay of reduction of acidity; and not only so, with such delay there is also a lessening in the rate of emptying from the stomach. Ligature of other sources of alkali, such as the saliva or the bile, was followed by much less evident diminution of acidity. The fact, too, that the concentration of chlorides in the stomach remains constant shows that reduction of acidity is not due to absorption of the acid by the gastric mucous membrane. In absence, however, of pancreatic juice the acidity can be to some extent lowered by the abundant influx of bile and intestinal juice. Apparently there is a general law which extends to all cases. A portion of the strong acid fluid passing from the stomach into the intestine provokes an abundant secretion, especially of the pancreatic juice; it, moreover, provokes antiperistalsis in the intestine, which drives the alkaline secretion into the stomach until a

sufficient quantity accumulates which is capable of bringing the acidity to the level of about 0.15 per cent. HCl. It is thus easy to reconcile the results obtained by physiologists and clinicians. The initial acidity is 0.5; the final acidity is about a third of this, a degree at which protein digestion in the stomach is most favoured. These facts suggest an explanation of the rapid emptying of the stomach, which radiologists note as indications of duodenal irritation. Many other clinical findings may be illuminated by these useful observations.

PARLIAMENT reopened on Tuesday last, the proceedings being mainly Government business.

The Hunterian Oration will be delivered at the Royal College of Surgeons of England, Lincoln's-Inn Fields, on Monday, Feb. 15th, at 4 o'clock, by the President, Sir W. Watson Cheyne, who has chosen as his subject *The Treatment of Wounds in War*.

THE CHADWICK LECTURES ON WAR AND DISEASE.¹

THE last of the three lectures organised by the Chadwick trustees was delivered at the Royal Society of Arts on Jan. 29th by Colonel F. M. SANDWICH, M.D., the subject being "*The Great European War*." The chair was occupied by Sir H. TRUEMAN WOOD, secretary of the Royal Society of Arts, and the attendance was again a large one.

Colonel SANDWICH said that every campaign had its peculiar medical dangers, and in such a gigantic war as the present one the dangers were manifold, depending on the climate, the people, and even the soil in the fighting areas. Whilst cholera and other diseases were menacing the German and Russian troops, we could recognise the fact that the attention given to hygiene, besides the value of antityphoid inoculation, saved our troops from great loss due to disease. The sick-rate of our troops now at the front was only 3 per cent., and among the Indian troops it was said to be even lower. The following figures relating to typhoid fever were now issued. In the first 421 cases of typhoid fever among the British troops in this campaign 305 were in men who had not been inoculated. In the 421 cases there were 35 deaths, 34 of them in men who had not been inoculated within two years, the other was in a man who had been inoculated once.

One source of trouble in the past had been wound poisoning caused by dirt, and resulting in gangrene and tetanus. The latter had attacked the wounded of our own and the enemy in about equal degree. Generally its spasms were more exhausting than painful; but there was great suffering when the patient had an extensive wound, and the spasms might produce agonising pain. In the worst cases a fatal end was generally reached on the third day, and the symptoms of the disease usually commenced about ten days after the injury. When this interval was abbreviated the case seldom recovered. In the Aisne district tetanus was common among the ordinary population. Brilliant results had followed the use of antitetanic serum prophylactically. The earlier the prophylactic dose was given the more certain was its good effect, but by the time the symptoms were well established the disease had made great progress. The practice now was the following. On the reception of a wound the first field-dressing, consisting of a pad of gauze, was applied by a surgeon, a comrade, or by the patient himself. On arriving at the field ambulance this dressing was changed and the patient removed to the clearing hospital, where the wound was cleaned, if possible, and painted freely with a solution of iodine in spirit. Where needed, the dressing was repeated during the journey to the column or base. Since November a prophylactic injection of antitetanus serum was given to all wounded either at the clearing hospital or the field ambulance. Thanks to the generosity of two anonymous

donors, a much-needed improvement in the medical service had lately been added. Hitherto each man had not, like the French soldier, carried his own iodine, but now he did so, in a little glass ampoule, put up by English manufacturers. The importance of this provision it was difficult to overrate.

Gangrene had also claimed its victims in this war owing to the soiling of the wounds, the causal bacillus being that responsible for malignant oedema. The work of Pasteur and Lister finally disposed of the idea that "wound fever" and "hospital gangrene" were spontaneously generated. In 1868 the mortality after amputations in France was 60 per cent.; and a well-known surgeon at the Charité Hospital said, "When an amputation seems necessary think ten times about it, for, too often, when we decide upon an operation we sign the patient's death-warrant." The bacillus of gas gangrene, being an anaerobe, did not infect superficial wounds, but multiplied in deep wounds and lacerated tissue. He described the usual course of a case of gas gangrene and narrated a typical instance. The subjects of it must be strictly isolated from other wounded men. In the Turkish War of 1877 the Turkish and Greek doctors in charge had no disinfectants except a few basins of quicklime. Repeated attempts had been made to supply a vaccine to counteract the bacillus of gangrene, but nothing had yet been achieved to warrant its use on man.

Frost-bite was always liable to occur among troops in cold weather, especially when a high wind prevailed; and if frost-bite did not receive prompt attention it might end in gangrene; and the patient might not be aware of the transition because the freezing process was not a painful one, though that of inducing the blood to return to the part was attended with pain. Sudden warmth killed the tissue and thus precipitated gangrene. In January, 1878, the cold was so intense that 18 of Baker Pasha's sentries were frozen to death in one night, and it became necessary to change the sentries every 15 minutes. Some of the cases of frost-bite in the campaign were grotesque in their ghastliness. Our well-fed and well-clothed soldiers were not likely to suffer so severely from frost-bite, especially as the women of England had shown a veritable passion for knitting warm articles for the soldiers. The problem as to the best clothing for the men in the cold, wet trenches would not be solved by supplying waders, for occasions arose when the soldiers had to move quickly, either in attack or retreat. Perhaps the rubbing of some kind of grease (which would not mix with water) all over the body would be found of some avail. This war differed from other campaigns in its uninterrupted violence. In other struggles there had been lulls during which the combatants could rest and recuperate after periods of excessive strain, for those who had not been at the firing line could not realise the effect on the nerves produced; and the men could only be ensured some respite by organising relays of relief troops. When the first batch of 230 wounded arrived at one of the London hospitals they were in such an exhausted condition that very little could be done for them beyond getting them to bed quickly. They slept the sleep of utter exhaustion, and next day had to be aroused to be washed. But after the first 30 hours they suffered from sleeplessness; they slept lightly, and frequently awoke with a start and shouted, believing they were still being attacked in the trenches. They were not lacking in courage, but the nerve strain had been excessive, though a complaint was practically never heard. Sometimes the shell fire had caused transient paralysis of the lower limbs, loss of sensation to heat and cold, and defective vision.

Dr. Sandwith spoke of the plague of vermin which attended campaigns. Bugs were bearers of certain tropical diseases, and lice were believed to convey dread diseases which had played havoc in camps in the past. The psychic feeling of disgust at harbouring these pests in men who had been accustomed to clean living was a factor to be reckoned with. It was difficult to cope with the trouble, but instructions had been issued to the troops which it was hoped would minimise it.

Relapsing fever was a febrile illness due to spirochæta in the blood. The mortality from it was not high, but the attendant weakness incapacitated the patient for a long time. Lice had long been suspected as the carriers of relapsing and typhus fevers, but an important factor in the process seemed to be the scratching of the irritating lesion. Lice must be regarded as a menace to ultimate victory, and

¹ Reports of the first and second lectures appeared in *THE LANCET* of Jan. 23rd (p. 105) and 30th (p. 247) respectively.

we could not contemplate defeat by disease any more than by armies; hence every soldier should be impressed with the necessity of ridding himself of these pests.

This lecture was also illustrated by some very interesting slides, and the thanks of the audience, voiced by the chairman, were very warmly accorded to Dr. Sandwith.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

MEETING OF COMITIA.

A COMITIA was held on Jan. 28th, Sir THOMAS BARLOW, Bart., K.C.V.O., the President, being in the chair.

The following gentlemen having passed the required examination were admitted Members of the College: Jivraj Narayan Mehta, M.D. Lond., L.R.C.P., John Tattersall, M.D. Lond., L.R.C.P., and William Wilkinson Uttley, M.B., Ch.B. Vict., L.R.C.P. (Lymm, Cheshire).

Licences to practise physic were granted to 114 gentlemen who had passed the necessary examinations.

Diplomas in Public Health were granted jointly with the Royal College of Surgeons of England: Kishori Lal Chandry, M.B., B.S. Punjab, Punjab and University College; Noormahomed Kasembhai Chohan, L.M. & S. Bombay, Bombay and Cambridge; Herbert William Fankhauser, M.B., Ch.B. Melb., Melbourne and R.I. Pub. Health; Thomas Marlin, M.D., Ch.B. Glasg., Glasgow and University College; Lucy MacBean Ross, M.B., Ch.B. Glasg., Glasgow and University College; and Andrew James Shinnie, M.D., Ch.B. Aberd., Aberdeen and University College.

The PRESIDENT announced that he had appointed Dr. Sidney Coupland to be the Harveian orator for 1915, and Dr. J. Michell Clarke to be the Bradshaw lecturer for 1915. Also that the Council had appointed Dr. Samson G. Moore (medical officer of health of Huddersfield) to be the Milroy lecturer for 1916.

The following communications were received. From the Secretary of the Royal College of Surgeons of England, dated Dec. 12th, 1914, and Jan. 15th, 1915, reporting proceedings of the Council of that College on Dec. 10th, 1914, and on Jan. 14th, 1915, respectively.

Dr. A. G. Barrs, Dr. H. G. Turney, Dr. H. Morley Fletcher, and Dr. L. Humphry were elected councillors.

Sir Francis Champneys, Bart., was elected a Representative of the College on the Central Midwives Board for one year from April 1st next.

Mr. Mark Lemon Romer, K.C., was elected a senior standing counsel to the College in the place of Lord Parmoor.

Sir Dyce Duckworth, Bart., was re-elected as Representative Member of the Court of the University of Liverpool. Dr. S. H. West was re-elected a Representative Member of the Court of Governors of the University of Birmingham.

A report was received and adopted from the representative of the College on the General Medical Council.

After some further formal business the PRESIDENT dissolved the Comitia.

TYPHUS FEVER IN DERRY.—An outbreak of typhus fever has occurred in Derry to the extent of nine cases in the lower-lying badly drained parts of that city where there are many dry closets. It is hoped that the epidemic is now over.

THE WOMEN'S IMPERIAL HEALTH ASSOCIATION.—The annual meeting of this association was held at the offices at 7, Hanover-square, W., on Jan. 20th, when Dr. R. Murray Leslie took the chair. He reviewed the year's work of the association, the last five months of which had been largely influenced by the war. Among many other activities the association had undertaken the organisation of the Health and Social Section of the Women's Emergency Corps, and had registered over 1900 voluntary workers and placed 1364 of these in useful work. The association had also started a Women's Club. The chairman referred also to the many other branches of work, all of which had been proceeding satisfactorily. The annual report can be had on application to the secretary.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Fleet-Surgeon William Ernest Marshall has been placed on the Retired List (dated Jan. 20th).

The following appointments are notified:—Fleet-Surgeon: W. H. O. Garde to the *Revenge*. Surgeon: M. F. Caldwell to the *Vivid*, additional, for disposal. Temporary Surgeons: W. H. W. Cheyne to the *Soudan* Hospital Ship; J. S. Jobson to the *China* Hospital Ship; W. L. Anderson to the *Pembroke III* for R.N. Air Service; and F. A. Williamson to the *Pembroke*, additional, for disposal.

The undermentioned have been granted temporary commissions as Surgeons in His Majesty's Fleet:—David Revell Bedell-Sivright and George Stivala Aspinall.

ROYAL NAVAL RESERVE.

The undermentioned Acting Sub-Lieutenant has been promoted to the rank of Sub-Lieutenant:—Dated Dec. 2nd, 1914: Nigel Adrian Macqueen.

The undermentioned have been granted temporary commissions as Surgeons in His Majesty's Fleet:—Dated Jan. 26th: Weir Burns Cunningham and William Little Glegg. Dated Jan. 27th: Alfred George Stewart and Dundas Simpson MacKnight.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon: T. Turner to the *Pembroke*, additional, for Chatham Hospital.

ARMY MEDICAL SERVICE.

Colonel Robert Porter is retained on the Active List under Article 120 Royal Warrant for Pay and Promotion, and to be Supernumerary (dated Jan. 31st).

ROYAL ARMY MEDICAL CORPS.

The undermentioned Captains to be Majors:—Dated Jan. 31st: Albert E. B. Wood, James B. Meldon, Charles Bramhall, and Henry T. Stack.

The undermentioned Lieutenants to be Captains:—Dated Jan. 28th: Basil H. H. Spence, William B. Laird, Robert Davidson, Herbert S. Blackmore, James M. Elliott, Francis R. B. Skrimshire, Douglas W. Bruce, Thomas E. Osmond, Richard T. Vivian, Edward G. H. Cowen, Leonard Buckley, William L. Webster, Edward B. Allnutt, Stanley P. Sykes, Harry C. Todd, Henry J. G. Wells, Ernest C. Deane, Frank S. Tamplin, Ivor R. Hudleston, William Stewart, Alexander G. J. MacIlwaine, and Arthur S. Heale.

The undermentioned officers, Home Hospitals Reserve, are granted the temporary rank of Captain:—Dated August 6th, 1914: J. E. Moorhouse. Dated August 14th, 1914: D. M. Barry. Dated Jan. 4th: A. B. Leakey.

The undermentioned to be temporary Captains:—Dated Dec. 28th, 1914: Temporary Lieutenant Robert Higham Cooper. Dated Jan. 6th: Charles Ravenscroft Stewart. Dated Jan. 15th: Henry Wynyard Kaye.

The undermentioned to be temporary Lieutenants whilst serving with the Red Cross Hospital, Netley:—Dated Jan. 19th: Donovan Blaise Pascall and Walter Gibson Marsden.

The undermentioned to be temporary Lieutenants:—Dated Oct. 12th, 1914: Alfred Squire Taylor. Dated Dec. 18th, 1914: Edward Forbes. Dated Jan. 1st: Robert Hilton Hutchinson, William Herbert Clements, and James Douglas Driberg. Dated Jan. 2nd: Ernest Leon Maunsell Hackett, Conwy Llewellyn Morgan, and Anthony Hagarty Corley. Dated Jan. 4th: Ralph Anderson Hughes. Dated Jan. 7th: Harold Benjamin Day, Harold Kempsey, Thomas Burns Marshall, Daniel Brough, Edward Verdon Russell Fooks, Thomas Langton Butler, George Fitzjames Darker, Herbert Eustace Clarke, Robert Wilkinson Greatorex, and Howard George Pesel. Dated Jan. 9th: Robert Cecil Leonard, Jerome O'Flynn, and Bernard Charles Tennent. Dated Jan. 10th: Arthur Riley, Frederick Harris, William Edgworth David, Walter Timothy James, Robert Kay Nisbet, and Thomas Marron. Dated Jan. 11th: Henry Speldevinde de Boer, George Alexander Connell Gordon, and David Heron. Dated Jan. 12th: Humphrey Rivers Pollock, Cyril Aubrey Smallhorn, Bernard Ernest Wall, Robert James D'Arcy Irvine, Finbar John Hunt, Albert Jones, Robert Francis Jones, Robert Yelverton Stones, and George Oliver Maw. Dated Jan. 14th: Arthur Hines. Dated Jan. 15th: Walter Winslow, Douglas Green, Arthur Charles Douglas Firth, Cecil Banting, Claude Hollingworth Philips, Thomas Joseph Kelly, Clive Justin Hicks Sharp, Charles Francis Orr White, Robert Campbell Begg, Ernest Stewart Dixon, and Maurice Mackenzie.

The undermentioned relinquish their temporary commissions with the Allied Forces Base Hospital:—Dated Feb. 1st: Captain Norman Duggan, Captain Sidney B. Radley, Lieutenant Douglas E. Derry, and Lieutenant Robert Henry Liscombe.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant William O. Lodge resigns his commission.

TERRITORIAL FORCE.

Royal Army Medical Corps.

Scottish Horse Mounted Brigade Field Ambulance: John Eaton Lascelles to be Lieutenant.

3rd West Riding Field Ambulance: Lieutenant Ernest White, from Attached to Units other than Medical Units, to be Lieutenant.

3rd Southern General Hospital: Major Arthur P. Dodds-Parker to be Lieutenant-Colonel (temporary). Captain Robert Ritson to be Major (temporary).

1st London (City of London) Sanitary Company: William Dyer Frazer (late Surgeon-Captain, Rand Rifles) to be Lieutenant.

2nd South-Western Mounted Brigade Field Ambulance: Major John R. Benson to be Lieutenant-Colonel (temporary).

South-Eastern Mounted Brigade Field Ambulance: Charles Edward Silvester (late Surgeon-Captain, Surma Valley Light Horse) to be Lieutenant.

1st Northern General Hospital: James Leslie Wilson (late Second Lieutenant, Unattached List for the Territorial Force) to be Captain, whose services will be available on mobilisation.

2nd Southern General Hospital: Robert James Irving to be Lieutenant.

4th Scottish General Hospital: Lieutenant James H. Martin, from Attached to Units other than Medical Units, to be Captain, whose services will be available on mobilisation.

Sanitary Service: Major Charles M. Fegen, from 2nd London Sanitary Company, to be Sanitary Officer of the 2nd London (Reserve) Division.

Supernumerary for Service with the Officers Training Corps: The undermentioned to be Lieutenants for service with the Medical Unit, University of London Contingent, Senior Division, Officers Training Corps: William Gilliat, Richard Drummond Maxwell, and John Henry Ryffel.

North Midland Mounted Brigade Field Ambulance: Arthur Wellesley McClelland to be Lieutenant.

3rd Home Counties Field Ambulance: Captain William D. Sturrock, from the Unattached List for the Territorial Force, to be Captain (temporary).

3rd South Midland Field Ambulance: Lieutenant James G. McLannahan, from Attached to Units other than Medical Units, to be Lieutenant.

Attached to Units other than Medical Units.—Captain Lawrence C. V. Hardwicke is seconded. Lieutenant Gerald R. Rickett to be Captain (temporary). Lieutenant George F. R. Smith is seconded. To be Lieutenants: Joseph Patrick Fagan and Evan David Richard. Lieutenant Patrick Black and Lieutenant Kenneth Mackinnon resign their commissions.

Unattached List for the Territorial Force.—Second Lieutenant James L. Wilson resigns his commission.

Officers Training Corps.

University of London Contingent, Senior Division: Lieutenant Philip Henry Mitchiner to be Captain (temporary).

TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon the undermentioned officers of the Territorial Force:—Army Medical Staff: Colonel James Harper. Royal Army Medical Corps: 1st West Lancashire Field Ambulance: Lieutenant-Colonel John J. O'Hagan and Major Henry D'A. Blumberg (attached to the 7th Battalion, The King's (Liverpool Regiment)).

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The November, 1914, issue of this journal, publication of which has been delayed owing to the war, contains among articles of topical interest a communication from Lieutenant-Colonel C. B. Lawson and Lieutenant Beckwith Whitehouse detailing the method of treating acute emphysematous gangrene by injection of hydrogen peroxide, which was referred to in a leading article in our columns last week. Colonel Sir Anthony A. Bowlby and Lieutenant S. Rowlands's joint report on gas gangrene, which was published in THE LANCET of Nov. 28th, 1914, p. 1265, also finds a place in this issue. Captain R. G. Archibald contributes a preliminary report on Some Further Investigations on Kala-Azar in the Sudan, and Colonel T. W. Gibbard discusses the apparatus required and the technique employed in the intravenous injection of neosalvarsan in concentrated solution.

DEATHS IN THE SERVICES.

Lieutenant-Colonel Robert Burnet, 1st Wessex Field Ambulance, Territorials, on Jan. 28th, the result of an accident while riding between Newton St. Cyres and Exeter. Lieutenant-Colonel Burnet was medical officer of health for Cornwall.

Colonel Richard Exham, C.M.G., late R.A.C.M., recently, in his sixty-seventh year. He entered the army in 1871, and served in the South African War, 1899-1901, when he was principal medical officer to the Natal Field Force, and was present at the defence of Ladysmith (twice mentioned in despatches, and Queen's medal with four clasps). He retired in 1903.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last census, 8938 births and 6693 deaths were registered during the week ended Saturday, Jan. 30th. The annual rate of mortality in these towns, which had declined from 21.3 to 18.0 per 1000 in the four preceding weeks, rose in the week under notice to 19.2 per 1000 of their aggregate population, estimated at 18,134,239 persons at the middle of 1914. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 18.9, against 19.6 per 1000 in London. The annual death-rate last week ranged from 9.9 in Swindon, 10.3 in Edmonton, 11.3 in Grimsby, 11.7 in Hornsey, and 13.1 in Wimbledon, to 28.8 in Merthyr Tydfil, 29.1 in Wigan, 30.0 in Ipswich, 30.3 in Rotherham, and 23.6 in Carlisle.

The 6693 deaths from all causes were 434 in excess of the number in the previous week, and included 483 which were referred to the principal epidemic diseases, against 454 and 479 in the two preceding weeks. Of these 483 deaths, 191 resulted from measles, 99 from whooping-cough, 77 from diphtheria, 73 from infantile diarrhoeal diseases, 31 from scarlet fever, and 12 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1.4 per 1000, and coincided with that recorded in the previous week. The deaths attributed to measles, which had been 183, 195, and 206 in the three preceding weeks, fell to 191 last week, and caused the highest annual death-rates of 1.8 in Preston, 2.1 in St. Helens, 2.3 in Newport (Mon.), 2.6 each in Stockton-on-Tees and Gateshead, 2.7 in Plymouth, 3.1 in Newcastle-on-Tyne, 4.0 in Rotherham, 5.1 in Wigan, and 7.0 in Darlington. The deaths referred to whooping-cough, which had been 93, 76, and 93 in the three preceding weeks, further rose to 99 last week; the highest recorded rates from this cause were 1.4 in Bristol, 1.6 in Brighton, 1.7 in Tynemouth, 1.9 each in Dewsbury and Barnsley, 2.0 in Sunderland, 2.4 in Rotherham, 2.8 in Bootle, and 4.3 in Merthyr Tydfil. The fatal cases of diphtheria, which had been 77, 63, and 83 in the three preceding weeks, fell to 77 last week, and included 16 in London, 5 in Sheffield, 4 in Birmingham, and 3 each in Manchester, Bradford, and Newcastle-on-Tyne. The deaths of infants (under 2 years) attributed to diarrhoea and enteritis, which had declined from 86 to 62 in the four preceding weeks, rose to 73 last week, of which 21 were recorded in London, 5 each in Liverpool and Leeds, and 4 in Manchester. The deaths referred to scarlet fever, which had been 35, 34, and 23 in the three preceding weeks, rose to 31 last week, and included 6 each in London and Manchester, 4 in Birmingham, and 2 in Plymouth. The fatal cases of enteric fever, which had been 15, 11, and 12 in the three preceding weeks, were again 12 last week, of which 2 each occurred in Stoke-on-Trent, Bolton, and Newcastle-on-Tyne.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 5035 to 3836 in the nine preceding weeks, had further fallen to 3647 on Saturday last; 326 new cases were admitted during the week, against 321, 338, and 308 in the three preceding weeks. These hospitals also contained on Saturday last 1632 cases of diphtheria, 126 of measles, 51 of enteric fever, and 28 of whooping-cough, but not one of small-pox. The 1757 deaths from all causes in London were 160 in excess of the number in the previous week, and corresponded to an annual death-rate of 20.3 per 1000. The deaths referred to diseases of the respiratory system, which had declined from 562 to 417 in the four preceding weeks, rose to 450 in the week under notice, and were 25 above the number recorded in the corresponding week of last year.

Of the 6693 deaths from all causes, 245 resulted from different forms of violence and 519 were the subject of coroners' inquests, while 1900 occurred in public institutions. The causes of 63, or 0.9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Sheffield, Leeds, Bristol, West Ham, Bradford, and in 65 other smaller towns. Of the 63 uncertified causes 15 were registered in Birmingham, 7 in Liverpool, 6 in Gateshead, 3 each in Nottingham, St. Helens, and Darlington, and 2 each in London, Southend-on-Sea, Rochdale, Halifax, Sunderland, and Tynemouth.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1196 births and 1009 deaths were registered during the week ended Saturday, Jan. 30th. The annual rate of mortality in these towns, which had been 24.5, 22.8, and 21.7 per 1000

in the three preceding weeks, rose to 22.4 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 22.9, against 18.9 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 8.8 in Motherwell, 15.2 in Clydebank, and 16.2 in Perth, to 28.4 in Coatbridge, 33.5 in Dundee, and 39.5 in Falkirk.

The 1009 deaths from all causes were 32 in excess of the number in the previous week, and included 128 which were referred to the principal epidemic diseases, against 92 and 98 in the two preceding weeks. Of these 128 deaths, 82 resulted from whooping-cough, 15 from infantile diarrhoeal diseases, 12 from scarlet fever, 10 from diphtheria, 6 from measles, and 3 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2.8, against 1.4 per 1000 in the large English towns. The deaths attributed to whooping-cough, which had increased from 28 to 58 in the five preceding weeks, further rose to 82 last week, of which 45 occurred in Glasgow, 25 in Dundee, 4 in Edinburgh, and 2 each in Aberdeen, Leith, and Motherwell. The deaths of infants (under 2 years) referred to diarrhoea and enteritis, which had been 17, 7, and 8 in the three preceding weeks, rose to 15 last week, and included 8 in Glasgow and 2 in Dundee. The fatal cases of scarlet fever, which had been 13, 9, and 16 in the three preceding weeks, fell to 12 last week, of which 6 occurred in Glasgow and 2 in Paisley. The deaths attributed to diphtheria, which had been 21, 10, and 8 in the three preceding weeks, rose to 10 last week, and included 3 in Glasgow and 2 each in Edinburgh and Aberdeen. The deaths referred to measles, which had been 7 in each of the three preceding weeks, were 6 last week, and comprised 3 in Dundee, 2 in Greenock, and 1 in Paisley. The 3 fatal cases of enteric fever were registered in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 265, 275, and 238 in the three preceding weeks, rose to 272 in the week under notice; 30 deaths resulted from different forms of violence, against 35 and 30 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,212,380 persons at the middle of this year, 680 births and 575 deaths were registered during the week ended Saturday, Jan. 30th. The annual rate of mortality in these towns, which had declined from 27.8 to 24.0 per 1000 in the four preceding weeks, rose to 24.7 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 24.9, against 18.9 and 22.9 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 29.8 in Dublin (against 20.3 in London and 21.6 in Glasgow), 20.4 in Belfast, 26.5 in Cork, 21.5 in Londonderry, 20.3 in Limerick, and 32.3 in Waterford, while in the 21 smaller towns the mean death-rate was 22.9 per 1000.

The 575 deaths from all causes were 18 in excess of the number in the previous week, and included 32 which were referred to the principal epidemic diseases, against 48 and 35 in the two preceding weeks. Of these 32 deaths, 11 resulted from whooping-cough, 8 from infantile diarrhoeal diseases, 4 each from measles and scarlet fever, 3 from diphtheria, and 2 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1.4, against 1.4 and 2.8 per 1000 in the English and Scotch towns respectively. The deaths attributed to whooping-cough, which had been 11, 10, and 9 in the three preceding weeks, rose to 11 last week, and included 4 in Dublin, 3 in Belfast, and 2 in Dundalk. The deaths of infants (under 2 years) referred to diarrhoea and enteritis, which had been 11, 14, and 4 in the three preceding weeks, rose to 8 last week, and comprised 5 in Dublin and 3 in Belfast. The fatal cases of measles, which had been 6, 12, and 15 in the three preceding weeks, fell to 4 last week, and comprised 2 each in Dublin and Belfast. The 4 deaths attributed to scarlet fever, of which 3 were registered in Belfast and 1 in Dublin, were equal to the average in the three preceding weeks. Of the 3 deaths referred to diphtheria, 2 were recorded in Cork and 1 in Kilkenny. The fatal cases of enteric fever occurred in Dublin and Clonmel.

The deaths referred to diseases of the respiratory system, which had been 139, 164, and 137 in the three preceding weeks, rose to 160 in the week under notice. Of the 575 deaths from all causes, 194, or 34 per cent., occurred in public institutions, and 12 resulted from different forms of violence. The causes of 19, or 3.3 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the English towns the proportion of uncertified causes did not exceed 0.9 per cent.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

French Medical Men in the Army.

Professor Tuffier, at the annual meeting of the Société de Chirurgie, recalled the era of 1871, when the same enemy defiled the soil of France, and paid a well-merited tribute to the devotion of the French Military Medical Service. He expressed a cordial greeting to those doctors who had the perilous honour of serving at the front, and made a rapid survey of the work done and the courage displayed by the medical service since the beginning of the war. At the end of December, of the 14,000 French surgeons on military duty 6500 were still serving with the armies, while 1300 had been placed *hors de combat* (93 killed, 260 wounded, 440 missing, and 507 invalided). M. Dercle, médecin-major of the first class, who is now under treatment, sustained near Mézières 97 shrapnel wounds. Medical officers have been mentioned in orders 155 times, and there have been awarded to them 15 ribbons and 63 crosses of the Legion of Honour, also 11 military medals. Professor Tuffier related what he had seen and heard at the front concerning medical officers who, having fallen into the hands of the German medical officers, were robbed, not only of their canteens and surgical instruments, but of their cloaks and their crosses, everything, even their spurs, being taken from them. He also described how a German officer at Mercy-le-Haut robbed and tried to murder an auxiliary medical officer, an interne of the hospitals, and told how a German patrol of Pomeranian infantry murdered 40 wounded.

The Health of Paris.

The mobilisation of a large number of medical men for the armies gave rise to a dread of what might happen from a paucity of medical practitioners. This fear, however, has proved unfounded. It is true that medical men of all ages are liable to mobilisation, but there still remain at their civil posts those on the Retired List, the auxiliaries not called up, and those yet mobilisable whose class has not yet been called on and who have not applied to be attached for service, as well as a considerable number of foreign medical men. The hospitals go on as usual in all their departments, the absent medical staff being replaced by an increasing number of *confrères*. The general condition of Paris is, moreover, excellent, and this is due to several causes: there are fewer vehicles in the streets, and hence fewer floating microbes; the consumption of alcohol has markedly diminished, consequently there is less drunkenness. Notwithstanding the mass of refugees, naturally in a state of great depression and frequently accommodated most uncomfortably, the number of appeals for free assistance is not in excess of what was the case before the commencement of hostilities. Evidently the medical men of Paris cannot spare themselves, but they are not worrying over it. The drugs that have become exhausted are easily replaceable, for the German products which before the war were used in large quantities all have their French equivalents.

Medical Life in Paris.

Before the Académie de Médecine M. Sieur has urged the necessity for no delay in the disinfection of wounds, particularly shell wounds, to

prevent tetanus. Ragged wounds especially must be trimmed and cleaned. M. Dalimier reported that he had successfully treated with autovaccines prepared at the Institut Pasteur certain cases of pus-infected wounds that had proved refractory to every other treatment. M. F. Debat said that he had used Jacquet's biokinetic method in the treatment of frost-bites, and that by this means soldiers carried to his service who were incapable of walking, whose feet were cedematous and ulcerated, were completely cured in eight days. M. Jousseau proposed the use of tobacco smoke against body lice. Another method is to place the clothing infested with these parasites on an ant-hill. The ants will make short work of the parasites. M. Quénu showed that gaseous gangrene does not appear to be a clinical morbid entity, but constituted the last stage of all gangrene of wounds. It is therefore important to deal with such wounds energetically from the very onset of the gangrene, even when the general aspect is benign. Trimming the wound is the first measure. Injections of oxygenated water or of oxygen have not established their value and can be recommended only as adjuvants to trimming. This process should be practised without general anaesthesia, and should be followed by disinfection of the wound. In 12 new cases in which M. Quénu has used this method he has had no occasion to resort to amputation. M. Belbèze showed that colloidal gold finds a therapeutic indication in the surgery of war whenever serious infections are found, whether operative or not, generalised or localised, and in extended suppurating wounds. M. Lannos and M. Chavanne have shown that gun deafness may be related to lesions of cerebral origin or to psychic troubles, or that it may attack the labyrinth itself and be accompanied by fracture of the cranium or of the petrous bone, by ruptures of the tympanum, or again may present no other manifestation than a concussion of the labyrinth. M. Darier pointed out that, speaking generally, serums are indicated in acute infections with fulminant and febrile manifestations, while vaccines are more suitable in atonic, chronic, and well-localised conditions, in the treatment of ocular tuberculouses. Before the Société de Chirurgie M. Michaux related his method of treating penetrating wounds of the chest in the surgery of war. From the author's observations it is clear that hæmothorax following on penetrating wounds of the chest from gunshot and other wounds of warfare presents itself under two different aspects: the one serious, in which death ensues in a few days, the other of less grave prognosis and susceptible of cure by good drainage and postero-inferior thoracotomy. M. Sencert dealt with the treatment of penetrating wounds of the abdomen in ambulances at the front. In view of the impossibility of interfering under satisfactory circumstances and with adequately sterilised material, the author says that one should content oneself in such cases with immediate and absolute immobilisation, withholding all food. Cure will result in those cases in which a clot obliterates the bleeding vessel or in which adhesion closes a perforated coil of intestine. It is physically impossible for the surgical personnel of the ambulance, when in less than a day the necessary surgical attention has to be given to from 250 to 300 wounded, to devote the greater part of the time to doing a few laparotomies. Out of 66 wounded abdomens that M. Sencert has seen treated in this way, of which it was possible to

follow up 58 completely, 45 died and 13 were cured. M. Auvray has done since the end of August 25 trepannings for gunshot wounds of the cranium. Nine cases were of wounds relating exclusively to the cranial vault, and 16 cases in which the cranial walls, the meninges, and the brain were involved.

FLOUR PRICES AND BREAD MANUFACTURE.

To the Editor of THE LANCET.

SIR,—With reference to the article in THE LANCET of Jan. 30th on the Dearer Loaf I should like to point out that, assuming a continued increase in the price of wheat, our consideration ought to be given not only to the material from which the loaf is made, but also to the actual method of its manufacture. In this connexion aeration of the dough, as distinct from raising it by yeast, is worthy of our serious attention. It is a well-known fact that in the raising of dough by fermentation a considerable loss of nutritive material takes place. This loss has been estimated by different observers at from 2'1 to 4'2 per cent., and is mostly represented by the production of alcohol which, since the finished loaf rarely contains more than 0'3 per cent. of this substance, is practically entirely wasted. Graham estimated that 300,000 gallons of alcohol were lost yearly in London in this way. With regard to the loss of bread, Liebig calculated that by using fermentation for the raising of the dough in Germany sufficient bread was lost daily to provide the then German army with their daily bread ration. If we consider a population of 40,000,000 and assume that it requires half a pound of bread per head per diem, and that the loss of material by the fermentation process of dough raising is 1 per cent., we shall find that if we use aeration for the dough raising we shall be able to make in the latter case enough bread from the same quantity of flour to feed an extra 400,000 individuals at the same rate of consumption per diem. There are many methods of aeration, all of them technically quite simple. There are no facts tending to show that aerated bread is less digestible or less nutritious than ordinary bread, and the process of aeration is applicable to all kinds of flour. To many palates aerated bread has a less appetising taste than ordinary bread, but, *inter arma silet gustus*.

I am, Sir, yours faithfully,

F. W. TUNNICLIFFE.

Harley-street, W., Feb. 2nd, 1915.

TUBERCULIN TREATMENT OF PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—It is gratifying to find from Dr. N. D. Bardswell's article on the Value of Tuberculin, published in THE LANCET of Jan. 9th, that he has joined the small band of protagonists of the method.

The outstanding, and indeed the only unchallengeable, figures of his article are, of course, those referring to the bacillary findings, which are

tantamount to a statement that, no matter how rigidly controlled such figures may be, it is impossible to evade the fact that tuberculin, judged even from the immediate results of a few months' treatment, is of considerable therapeutic value—a fact which, by the way, suggests that, in the majority of cases at least, a trial of this treatment is not only justifiable but definitely indicated. The tables of general results, which admittedly do not point the same moral, are unfortunately inadmissible as scientific evidence. In the first place it is generally recognised that clinical examination alone is insufficient evidence on which to found definite statements as to arrest, and that the gross, unstandardised changes on which are based such elastic terms as "much improved," "improved," &c., are to be found in the majority of cases (tuberculin-treated or not) suddenly translated from normal to sanatorium existence; this, apart from the fact that within a few weeks of dismissal these judgments might have to be entirely altered. Moreover, Dr. Bardswell, whilst attempting to mix incompatibles—to wit, "arrests" and "much improves"—has omitted to state (1) whether in all cases the diagnosis of T.B. + was made on identical methods of examination of sputum; (2) what the average stay in the sanatorium was in each group; and (3) the average duration of specific treatment in the tuberculin groups. More important still, he does not indicate what was the method of selection of tuberculin cases, and whether the selection and treatment were carried out invariably by the same person. If, as one part of the article seems to suggest, selection was made by actual trial injections, then a percentage of early and favourable cases must have been omitted from the tables, because the sensitive reaction of many such cases is notorious; if, on the other hand, selection depended on clinical signs or temperature or general condition on admission (and this so generally poor), then a percentage of advanced or slightly febrile cases must have been omitted, cases which are recognised to improve most astonishingly during a course of tuberculin. The question of administration, either by the same individual or at least by a series of unbiassed observers using identical methods, is the more crying that many of the recent reports "on the value of tuberculin" have really merited the title of reports "on the value of tuberculin when given tentatively" or "experimentally," or "grudgingly," or "in an amateur fashion." There is one other point which deserves notice, although perhaps it is a minor one, and it is that the dangers noted after reactions—i.e., extension of disease, increased activity, pleurisy and pneumothorax—are, unfortunately, as the Registrar-General will testify, the dangers of the disease itself. At the same time, one can cordially agree with Dr. Bardswell in his appeal for a more scientific and critical spirit in the investigation of the value of tuberculin, always keeping in remembrance that critical investigation ought, in point of time, to follow scientific observation, because even in the kingdom of therapeutics the critic does not of necessity constitute the artist.

I am, Sir, yours faithfully,

EDWARD G. GLOVER.

Salterley Grange Sanatorium, Jan. 18th, 1915.

** We had Dr. Bardswell's communication some time before its appearance, and take the responsibility for its tardy publication.—ED. L.

AORTIC AND MITRAL REGURGITATION.

To the Editor of THE LANCET.

SIR,—In an annotation in your issue of Jan. 30th (p. 244) you mention the proceedings of the Société Médicale des Hôpitaux of Paris, at a recent meeting of which society cases of aortic incompetency, occurring in soldiers returned from active service, were recorded. There can be no doubt as to the diagnosis in these cases, as the French physicians are such expert auscultators. But it would be of much interest to learn whether in those cases with aortic regurgitation who had successfully borne the exertions of severe fighting there was any evidence of mitral incompetence also.

I have before this pointed out the advantages which accrue to a patient who, having aortic regurgitant disease, has in addition mitral regurgitation. Dyspnoea is less urgent, and they perform muscular feats which are quite beyond those who only have aortic incompetence. And when one considers the close proximity of one segment of the aortic valve with the lower or right flap of the mitral valve, it is difficult to know why a rheumatic poison which attacks an aortic valve does not extend its ravages to the mitral. I believe in a great number of cases this extension of endocarditis does take place, for the fibrous tissue of the two adjoining flaps is confluent. But in many cases this injury is limited to one valve only, the aortic, and in these I should have expected that dyspnoea would have been a disabling condition. I hope shortly to record some cases tending to confirm this point.

I am, Sir, yours faithfully,

Seymour-street, W., Feb. 1st, 1915. SEYMOUR TAYLOR.

FAITH AND ASTIGMATISM.

To the Editor of THE LANCET.

SIR,—Dr. S. Johnson Taylor's letter under the above heading in your issue of Jan. 30th is typical of the position taken up by those who, having no faith themselves, cannot realise there may be something in the claims of those who have faith, and he is therefore prepared to put down the results obtained by the latter to the effect of "black magic" acting on those whom he classes under the heading of that blessed word "neurotic," and considers that as a sufficient explanation. I am quite sure those of us who do believe in prescribing very low cylinders for constant wear do not consider only the refraction as being the sole cause of insomnia; at any rate, it is my habit as a result of some years' experience in general practice to make inquiries on such details as constipation, digestion, &c.

As Dr. Taylor says, "the proof of the pudding," &c., may I quote the following case? Several years ago a patient, not a "neurotic," consulted an ophthalmic surgeon of repute; he was given a prescription 0.50 D. cyl. axis vertical each eye, and told that he had very slight astigmatism, and it was doubtful if it caused his symptoms (depression, headaches), so the glasses might be worn for three months, and then if no relief was obtained they could be left off (judging from your correspondent's letter one would imagine he was speaking). Naturally, the surgeon having doubt, the symptoms did not disappear. After the lapse of some years another surgeon was consulted. He found that the astigmatism was 0.50 D. in one and 0.75 D. in the other eye. Glasses of this strength

were prescribed for constant wear, with the result the patient's headaches and fits of depression ceased.

The fact is, these cases require a great deal more care to be taken in estimating the amount of refractive error and its correction than some surgeons are able or willing to give; it is not sufficient to do a retinoscopy, place the correcting lenses thus found in the trial frame, record the effect, and then write the prescription. The objective examination is only a means to an end; the end is the result obtained subjectively, and to get this perfect entails investigation not only with the ordinary Snellen's type but with Prey's letters, and the astigmatic fan, checking the upshot with crossed cylinders, and finally, each eye having been tested separately, a trial should be made with both eyes together.

I am, Sir, yours faithfully,

Harley-street, W., Jan. 30th, 1915. REGINALD EVERSHERD.

FROST-BITE.

To the Editor of THE LANCET.

SIR,—In the various articles on frost-bite no really specific treatment has been suggested, and I venture to call attention to a remedy which I and my colleagues, Dr. P. G. Lewis, Dr. J. H. F. Wilgress, and Dr. T. Streatfeild, have found effective at the Army Nursing Homes at Folkestone. Peroxide 5 per cent. solution with tincture of iodine 1 drachm to the pint, applied as a compress for 12 hours, followed by dry boracic wool bandages. These applications relieve the pain, and the capillary circulation is improved, the sores are healed, and the sensation in the toes soon returns. Tried side by side with other remedies, this procedure has given far and away the best results.

Many of the cases appear to be caused by constriction of the vessels, due to wet and contracted garments. This bears out the theories of Sir Alfred Keogh and Mr. A. W. Mayo-Robson. The oedema and condition generally is more like that produced by long bandaging, and those who suffer most have generally been standing a long time in wet trenches, a factor predisposing to constriction and oedema, thus rendering the tissues vulnerable to cold. This treatment is excellent for chilblains also.

I am, Sir, yours faithfully,

Folkestone, Jan. 28th, 1915. LENNOX WAINWRIGHT.

THE LATE MR. BRYANT IN THE OUT-PATIENT ROOM.

To the Editor of THE LANCET.

SIR,—The obituary notice of Mr. Bryant in THE LANCET of Jan. 9th did not mention the excellent method adopted by this remarkable surgeon in his out-patient clinique. As one whose privilege it was to attend Thomas Bryant's out-patient room over a lengthened period and to receive considerable benefit therefrom I would like to place on record the plan he adopted in order to educate the student's powers of observation and tactile sense by having a succession of cases representing various phases and modifications of each particular class of disease, in the hope it may commend itself to other teachers.

The patients were classified in the waiting-room, and those of each class were given thick hexagonal cards of a special colour. Thus breast cases had red cards, venereal ones blue, deformities white, &c. Each set was seen in succession and the points in diagnosis, prognosis, and treatment insisted

upon. Breast cases may be taken as an example. Mr. Bryant would dilate on the importance of adhesion of the skin as an early sign of cancer, and we were shown how this was to be recognised and we were encouraged to bring out the significant puckering ourselves. A second case would show early implication of the glands, while a third would be an example of benign tumour. This thoroughness in clinical teaching quickened and sustained the student's interest in a remarkable degree, as was shown by the large and regular attendance of those who were desirous of acquiring real and lasting knowledge of surgery.

I am, Sir, yours faithfully,

Harley-street, W., Feb. 1st, 1915. CHARLES W. CHAPMAN.

THE PHARMACOPŒIAL DOSE.

To the Editor of THE LANCET.

SIR,—I am afraid your correspondent, Mr. George Foy, in your issue of Jan. 30th, has rather missed the point of my letter on the above subject. My main object was to secure clear and definite guidance from the medical profession in cases where it was found necessary to order more than the pharmacopœial dose of any active official drug. The method by which such guidance might be given was a subordinate consideration, which I felt was entirely a matter for the discretion of practitioners themselves. The practice indicated by Mr. Foy would be quite consistent with the suggestion I ventured to make.

I am, Sir, yours faithfully,

W. J. UGLOW WOOLCOCK,

Secretary, Pharmaceutical Society of Great Britain,
Bloomsbury-square, W.C., Jan. 30th, 1915.

LEECHES AND THE WAR.

To the Editor of THE LANCET.

SIR,—With regard to Professor A. E. Shipley's letter in THE LANCET of to-day's date, may I say that owing to a conversation I had in the autumn of last year with Professor Shipley, he very kindly interested himself to obtain for us a small supply (about 200) of *Limnatis granulosa*. Some of them are of an enormous size, but I am informed they are perfectly good to use, and that they will absorb from 4 to 6 drachms of blood.

We shall be pleased to supply any urgent order to brother pharmacists. The price is 18s. per dozen, and the proceeds are to be given to the Belgian Doctors' and Pharmacists' Relief Fund, so that it will be doing a good turn to our friends in distress.

I am, Sir, yours faithfully,

JOHN D. MARSHALL,

Managing Director, John Bell and Croyden,
Limited.

50, Wigmore-street, W., Jan. 30th, 1915.

BLUE PUS AS AN OMEN OF RECOVERY.

To the Editor of THE LANCET.

SIR,—The occurrence in a suppurating wound of blue pus, the product of the bacillus pyocyaneus, is a comparatively rare phenomenon, which can hardly be overlooked on account of the distinctive colouration of the dressings. During the past six months I have seen a dozen of these cases, occurring chiefly, but not invariably, among the wounded sent home from the front. The cases are usually compound septic fractures caused by shrapnel, and these when first seen discharge the "liquid mud" so commonly found in wounds infected in France and Belgium. After several

weeks of desperate illness a tinge of green is noticed on the previously mud-coloured dressings. In a couple of days the colour intensifies to a vivid bluish-green, which lasts a few days and then gradually fades, the total period of blue colouration averaging seven to ten days. Coincidentally with, or immediately following the appearance of the blue pus, the patient's condition improves, and by the time that the blue colouration has disappeared the wounds are covered with healthy granulations and convalescence is established.

This sequence has been almost invariable, so much so, indeed, that, given a patient desperately ill from acute sepsis, in whose wounds blue pus appears, I now venture to predict that the patient is on the road to recovery, and this prediction is nearly always verified. Clinically, the above phenomena suggest that the bacillus pyocyaneus has been present from the onset of the infection, but has been held in abeyance by the other pyogenic bacteria, and that as soon as the tissues begin to get the better of these bacteria the bacillus pyocyaneus is able to multiply rapidly. In none of the cases seen was there any suspicion of infection from a previous case showing blue pus; in fact, the blue pus was nearly always limited to a single patient in a ward filled with septic cases.

The above note has been written in the hope of eliciting: (1) the opinion of bacteriologists explaining why the appearance of blue pus, in intensely septic cases, is so often the harbinger of recovery; and (2) the experience of those surgeons who are treating the wounded from the front, as to whether they have found the appearance of blue pus in septic wounds to be a favourable omen.

I am, Sir, yours faithfully,

Plymouth, Jan. 27th, 1915. C. HAMILTON WHITEFORD.

LICE AND RHEUMATISM AMONGST SOLDIERS.

To the Editor of THE LANCET.

SIR,—The discomfort and pain caused by vermin and rheumatism to our soldiers are so great that every effort should be made to destroy these pests and relieve rheumatism. In the first edition of my "Pharmacology," published in 1885, I mentioned (p. 1105) five remedies for pediculi—viz., baking clothes to destroy the ova, mercury, anise, pyrethrum, and stavesacre. In the third edition, published in 1893, I added to this list chloroform, cocculus indicus, dalmatian flowers, essential oils, laurel leaves, petroleum, and quassia. The conditions of life on active service make it almost impossible to employ any parasiticide excepting in the form of an ointment. In the *Morning Post* of Jan. 14th there is a recommendation to employ mercurial ointment smeared upon one thick woollen string worn round the neck and another round the waist. This is a very simple method and seems worthy of a trial. In hospital practice the white precipitate ointment of the strength of 1 in 10 for the body and 1 in 5 for the pubis or else stavesacre ointment are more usually employed. Cantani, in his "Farmacologia Clinica," second edition, vol. ii., p. 212, recommends pyrethrum ointment as most efficacious against both forms of lice. It is made by mixing one part of pyrethrum with two of lard. Many essential oils, such as eucalyptus, seem to have a similar beneficial action to anise or pyrethrum. Anise is particularly useful in keeping away fleas, and an easy way of employing it is to carry about on one's person a small muslin bag filled with anise seeds.

In some cases, at least, of rheumatism sulphur is an exceedingly useful anti-rheumatic. Many years ago, with the conceit born of ignorance, I considered the statement that powdered sulphur worn inside the stocking is a cure for rheumatism to be only an old wives' fable. I learnt my mistake from a case which occurred in my own practice. I was seeing at fairly regular intervals for albuminuria a thoroughly skilled scientific chemist. One day he asked me to prescribe for his wife who was suffering from rheumatic pains in her hands which prevented her from sewing. This was to her a very serious matter as she added much to their joint income by embroidering altar cloths and the like. I gave him a prescription as requested, and at our next interview I asked him how his wife was. "Oh," he said, "she is quite well." I was much pleased at this, and was taking the credit for the cure to myself, when he told me that the medicine I had given her had done her no good at all, but a friend had told her to powder the inside of her stockings with sulphur and wear them all night. In a short time this completely cured her, and her husband said the sulphur must have been absorbed through the skin of her legs, passed through her body, and been excreted by the skin of her arms because her silver bangles became black. This remedy is simple, cheap, and easily applied, and might be useful in the case of our soldiers. I hardly think it could do any harm whatever, though I have no experience of the effect of sulphur continuously applied to the skin for some weeks together, but at any rate I think it is worth a trial.—I am, Sir, yours faithfully,

LAUDER BRUNTON.

New Cavendish-street, W., Feb. 3rd, 1915.

A MISUNDERSTANDING.

To the Editor of THE LANCET.

SIR,—I see a paper in THE LANCET of Jan. 30th by Dr. E. T. Jensen, and under the heading he is described as "Physician to the Special Hospital for Officers, Kensington Palace Green." This is a mistake. Dr. Jensen was one of the signatories to a letter to the press urging the need for such a hospital. But the staff of the hospital has been chosen from those who signed and from the rest of the profession. Dr. Jensen is not to blame in any way for the mistake. He was justified in thinking that the staff included all the signatories to the letter—in fact, I had in another letter alluded to the signatories as the staff. So the mistake is mine, and I regret to have placed Dr. Jensen in a false position.—I am, Sir, yours faithfully,

Eaton-square, S.W., Feb. 1st, 1915.

KNUTSFORD.

To the Editor of THE LANCET.

SIR,—Lord Knutsford has shown me his letter to you, and I quite appreciate his explanation.

I am, Sir, yours faithfully,

Harley-street, W., Feb. 1st, 1915.

E. T. JENSEN.

THE SHORTAGE OF RESIDENT MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—May I appeal through your columns for help in carrying on the work of the East London Hospital for Sick Children, Shadwell, E. It is possible there may be doctors who if they knew of the difficulties under which hospitals are now labouring would be willing to come into voluntary residence

and help them during this temporary crisis. We have exhausted all the regular methods of obtaining resident doctors, and unless we can procure such help we shall be compelled to close a large part of the establishment, which at the present time would be a great calamity for the sick children of this neighbourhood.

I am, Sir, yours faithfully,

W. M. WILCOX,
Secretary.

Shadwell, E., Feb. 1st, 1915.

THE BELGIAN STUDENT AND THE UNIVERSITY OF CAMBRIDGE.

To the Editor of THE LANCET.

SIR,—The medical profession, generous as ever, has supplied me with enough copies of "Gray's Anatomy" to satisfy the present needs of the Belgian students at Cambridge. The publisher and editor have increased my sense of gratitude by presenting some copies of the new edition.

I am, Sir, yours faithfully,

A. E. SHIPLEY.

Christ's College Lodge, Cambridge, Feb. 3rd, 1915.

FUEL SUPPLIES IN WAR TIME.

To the Editor of THE LANCET.

SIR,—The following two paragraphs from the current press deserve to be noted by all interested in the use of fuel, whether in the domestic grate, the steam boiler, or the factory furnace:—

Threatened Coal Famine in the Midlands.—Birmingham and the Midlands generally are threatened with a coal famine. Not only are householders menaced but manufacturers cannot obtain regular supplies, and if the present scarcity continues some of them will have to close down. A variety of causes have contributed to this, the most important of which probably is the deficiency of miners owing to enlistment.

Amsterdam, Jan. 28th.—An order to economise coal has been issued by the German railway administration at Essen. It has further been officially pointed out to housewives that coke is a much cheaper form of fuel than coal and gives a better heat.

Here is a point certainly where we may well learn from the enemy. It cannot be too widely known—not only by housewives but by factory managers and other large users of fuel—that there are in many districts full stocks of coke; that it is, at the same price per ton as coal, a much cheaper form of fuel, as a much larger percentage of its weight is readily combustible material; that in kitchen ranges "broken" coke is particularly useful; and that recent experiments have demonstrated that coke can be advantageously employed for steam raising with but slight variations in the furnace arrangements. It is therefore to the advantage both of the community and of the individual at the same time that the fullest possible use should be made of our coke supplies.

I am, Sir, yours faithfully,

Feb. 2nd, 1915. A STUDENT OF FUEL ECONOMICS.

THE National Association for the Prevention of Infant Mortality and the Welfare of Infancy has arranged for an advanced course of lectures on infant care, to be delivered at the Royal Society of Medicine, 1, Wimpole-street, at 5.30 P.M. on Mondays in February, March, and April. The lectures are for voluntary health workers, mothers, and nurses; arrangements will be made for consultations at selected centres, and those successful at an examination to be held at the close of the course will receive a certificate. All particulars can be obtained from Miss Halford, 4, Tavistock-square, London, W.C.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

A MEETING of the Central Executive Committee was held on Jan. 28th at the offices of the British Medical Association, when Sir Rickman Godlee and Mr. Meredith Townsend announced the despatch of the first box of instruments to Brussels. The box was delivered to the International Commission for Relief in Belgium at the Tunnel Wharf, Rotherhithe, and a Courier of the International Fund has taken charge of a letter to the Belgium Medical Committee in Brussels advising that Committee of the contents of the box and asking for reply as to whether similar consignments will be useful.

The question of providing clothes for the Belgian refugee doctors and pharmacists and their dependents was discussed at some length, and it was decided that attempts should be made to organise assistance in this direction. Certain steps have been taken; and those having wearing apparel in good condition are asked to communicate with Dr. Clément Philippe, 3, Hyde Park-street, London, W., where prepaid parcels may be sent. A voluntary group of sympathisers will assist in the distribution.

The payment of the fees for registration of the Belgian refugee doctors now to be admitted to the British roll of practice in this country was considered, but the Committee, speaking generally, did not consider that the Fund should pay these fees, because there seemed to be a discretionary power with the General Medical Council to reduce or remit them. A communication to this effect was made through the chairman of the Committee to the President of the General Medical Council.

PROVINCIAL ACTIVITY.

In the provinces great activity is being shown. A large meeting is being organised at Newcastle-on-Tyne by the local leaders of the medical profession; this meeting will be addressed by Professor Jacobs on Feb. 17th.

The University of Sheffield, the Sheffield Medico-Chirurgical Society, and the Sheffield Division of the British Medical Association having called a general meeting of the medical profession in Sheffield and the district to discuss the objects of the Fund, a committee was formed consisting of the following: Professor R. J. Pye-Smith, Professor R. Favell, Professor Sinclair White, Professor D. Burgess, Professor H. R. Dean, Dr. Sophia Wits, Dr. A. J. Hall, Mr. G. Wilkinson, Mr. Graham Simpson, Dr. A. G. Yates, Dr. H. Leader, Dr. A. W. Forrest, Dr. A. Forbes, Dr. R. Gordon, Mr. W. Longbottom, Dr. E. Hargreaves, Dr. C. Wiseman, Dr. J. Stokes, and Dr. R. W. Innes Smith. Dr. A. E. Naish, Westholme, 5, Clarkehouse-road, Sheffield, is acting as honorary secretary and treasurer to the Fund. A resolution was passed to instruct the committee to find out what offers of hospitality to refugees there might be from doctors in the district. Donations to the amount of £141 15s. were promised at the meeting.

From Birmingham a further list of subscriptions from both doctors and pharmacists has been received, and the Exeter Division of the British Medical Association (honorary secretary and treasurer, Mr. A. C. Roper, The Shrubbery, Exeter) makes a good first appearance. Both these local funds are still open.

In Manchester the movement will soon take force, as a strong local committee is being formed.

Dr. Archibald Donald, 2, St. Peter's-square, Manchester, is acting as honorary secretary, and a meeting of the local medical profession is projected immediately.

The Bradford Medico-Chirurgical Society has sent £25 to the Fund.

MEETING AT LIVERPOOL.

The meeting of the medical profession of Liverpool and district, held on the invitation of the President and Council of the Medical Institution to hear an address by Professor C. Jacobs, of Brussels, took place on Jan. 28th. It was most successful both in point of numbers and the enthusiasm displayed on behalf of the object for which it was convened. The title of Professor Jacobs's address printed on the circular sent to every medical practitioner in the neighbourhood was "Belgium and the Germans: the Belgian Medical Corps and the German Occupation."

The President of the Institution, Dr. E. W. Hope, occupied the chair. He introduced the subject in fitting terms, and admirably expressed the sentiments of those present who were eager to show their sympathy for Dr. Jacobs and his Belgian *confrères*. Dr. Hope alluded to the parlous condition in which the Belgian medical profession was, and pleaded that their condition could be materially alleviated by liberal subscriptions to the Belgian Doctors' and Pharmacists' Relief Fund through the Liverpool Medical Institution.

Professor Jacobs was received with sympathetic enthusiasm, the audience rising and acclaiming him. The first part of his address, "Belgium and the Germans," was delivered in French, slowly and deliberately, so that his hearers could readily follow him. In forceful language he repudiated the statements of the German professors, written to deny the national position of Belgium, declaring that on no occasion, and at no time, did the Belgians ever evince the slightest inclination to be taken under the protection of the Germans. He referred in scathing terms to their militarism, which had consummated the destruction of so many priceless monuments of human progress and civilisation, and in considering the present position of the Belgian medical profession and the German occupation declared that many medical men personally known to him had been shot or taken as hostages, while those who had been left alive had suffered plunder, rapine, and destruction of hearth and home. Surgical instruments, drugs, motors, horses, and even ornaments in their houses and their clothes had been stolen. The patients formerly able to pay their medical advisers were no longer in a position to do so and the source of professional income was strangled. "But I appreciate with all my heart," he said, "the noble efforts of the British medical profession and that of neutral countries to stem the rising tide of misery among their professional brethren." At the close of his address Professor Jacobs showed on the screen photographs he had taken himself of the various towns, once so *riantes*, now a heap of ruins.

A vote of thanks, proposed by Sir James Barr and seconded by Dr. Frank H. Barendt, was passed amid acclamation.

The Liverpool Fund now amounts to over £375, and it is expected that at least £500 will be raised.

THE BRITISH MEDICAL ASSOCIATION AND THE FUND.

At the meeting of the Council of the British Medical Association on Jan. 27th, the action of the treasurer and chairman of Council in authorising

a contribution by the British Medical Association of 100 guineas to the Belgian Doctors' and Pharmacists' Relief Fund was very heartily approved, as was also the action of the chairman of Council in causing an invitation to be addressed to the divisions and branches of the Association to open subscription lists. Already, as will have been seen from the lists published from time to time, many divisions have opened subscription lists and made important contributions to the central fund, and the list of subscriptions published below contains record of further contributions received through the divisions.

THE WEEK'S SUBSCRIPTIONS.

Conspicuous among the donations to the Fund announced this week is one of £100 from the Victoria (Australia) Medical Benevolent Association. The subscriptions from the pharmaceutical profession are coming in steadily. A subscription from the United Hospitals' Club reminds us of the time when St. Thomas's Hospital and Guy's Hospital lived face to face in the Borough.

The subscriptions received by Dr. Des Vœux up to Tuesday evening last, in addition to those previously acknowledged, amounting to £4480, and not including money received by the Scottish or Irish Funds, are as follows:—

Obituary.

BASIL GORDON MORISON, M.D. EDIN.

Dr. Basil Gordon Morison, whose death occurred on Jan. 28th at the age of 60, was the younger son of Surgeon A. C. Morison, of the Bengal Native Infantry in the Honourable East India Company's Service. His grandfather, Sir Alexander Morison, of Bankhead, Midlothian, was also a physician of London and Edinburgh. At the University of the latter city Dr. Morison received his medical education, graduating in 1878 with first-class honours and being *proxime accessit* to both the Ettles and Beaney prizes. After graduation he became a demonstrator of anatomy to Professor (now Principal) Sir William Turner. While in this position he did his work acceptably and wrote a paper on the Arrangement of the Azygos and Superior Intercostal Veins in the Thorax,¹ in which he described a new and almost constant venous junction. He then joined his elder brother in practice in the north of London, and it was, perhaps, unfortunate that he did so, for the quality of his work, his finished literary style, and his excellent draughtsmanship fitted him for scientific work and record. But the future of the young scientist is always uncertain and—one must live. He therefore settled in London in 1879.

Thirty-six years ago the centres of medical activity in the metropolis were less accessible from the suburbs than they are now. Islington at that time had but one medical society—the Islington Medical Society—which contained some members of the highest type of private practitioner. The meetings were, however, held in the private houses of members and were thus unsuitable for the exhibition of morbid specimens. Basil Morison, imbued with scientific ardour and cherishing a high ideal of his profession as a liberal calling, together with some others founded the Æsculapian Society in 1880, which practised the whole scientific method, observed all ethical proprieties, and Morison himself hoped it might also lead to the abolition of the practice of pharmacy by the family physician. But for his anxious care of the new society it would have foundered soon after it had been launched; thanks to it, it floated into deep water and still exists with a considerable membership, meeting at the Metropolitan Hospital and doing useful work in North London. Many of its members gathered in Abney Park Cemetery on Feb. 1st to pay their last respects to their friend and laid a corporate wreath upon his grave.

All Morison's scientific work, done amid the distractions of a practice carried on with punctilious conscientiousness and involving overwork, was of a high order, as is evidenced by his paper on Infantile Diarrhoea read at the annual meeting of the British Medical Association in Liverpool in 1883; by that on Symmetrical Cysts in the Cerebrum, communicated by him and the late Dr. Charlewood Turner to the Pathological Society of London, which was beautifully illustrated by Morison himself; and by numerous communications in the transactions of the Æsculapian Society, of which he was for a long time secretary, of which he had been President, and of which he was, at the time of his death, treasurer. His ideals of professional life caused him to offer a resolute opposition to the National Insurance Act. "For the vacillation of those who

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund and crossed Lloyds Bank, Limited. These will be acknowledged by post direct, and a list will appear in THE LANCET weekly.

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries acknowledges with thanks the receipt of surgical instruments kindly contributed by the following donors since the publication of the last list:—

Dr. Robert Sinclair, Dundee; Dr. R. H. Rowell, Newcastle-on-Tyne; Dr. H. Beckett-Overy, Lowndes-street, S.W.; Dr. H. M. Morgan, Lichfield; and Dr. Ethel Lampert, per Miss H. F. Gethen, Long Sutton, Winchfield.

HUNTERIAN SOCIETY.—The annual oration will be delivered by Dr. H. Russell Andrews on "William Hunter's Work on Midwifery" at 9 P.M. on Wednesday next, Feb. 10th, at the Barbers' Hall, Monkwell-street, E.C.

¹ Journal of Anatomy and Physiology, vol. xiii., p. 346.

should have been the guardians of the profession in this matter," writes one who knew Basil Morison well, "he entertained some scorn. He was the chairman of his division in opposing the panel system, and it is not too much to say that his strenuous exertions in this movement, with an underlying failure of health which he refused to acknowledge, materially hastened the crisis which resulted in his regrettable death."

While he was a man of great determination of character and with a singleness of purpose in the pursuit of right, Basil Morison was among his friends gentleness personified, and he probably had not an enemy. He was in the habit of remarking, especially during his last illness, when he at times suspected that his course was run, and expressed a little disappointment that it should be so, that, after all, it was what a man *did* that mattered, not what reward or recognition he obtained for his work. Though his material reward was not great, as so often happens in such cases, the inspiration of his example and his memory will be a force for good among his personal friends. Three months ago his heart began to fail acutely with an angina sine dolore, and he was removed to the residence of his brother, Dr. Alexander Morison, where he was under the joint care of his friends, Dr. Leonard Guthrie and Dr. George Johnston, and of his brother. Perfect rest eventuated in a promising improvement, and he contemplated spending some time with a friend in the country before trying to resume work. But accidental exposure on a boisterous day, when he was, brave to the last, rather imprudently but characteristically testing his degree of recovered power, always with a view to working again, caused a recurrence of cardiac failure, and after a week's struggle the end came. "He was," writes a personal friend, "a man of deep but unobtrusive religious feeling, attached more importance to the conclusions of St. Paul than to those of Renan and Strauss, and died as he had lived in the light of the life to come. It is well with him."

In 1887 he married Caroline, the eldest daughter of the late Colonel Herne, of the 103rd Regiment (Royal Bombay Fusiliers). She survives to mourn him with many attached friends.

The War.

MEDICAL PRISONERS OF WAR.

A FEW weeks ago we recorded the liberation and return to England of three officers of the Royal Army Medical Corps and two British Red Cross surgeons who had been taken prisoners by the Germans whilst attending wounded British and Belgian soldiers, and kept in captivity. Vivid accounts of the disgraceful treatment which several of these medical men received at the hands of the Germans appeared in the press at the time, but why the enemy should have chosen to release these particular medical men when there were so many others in exactly the same case has not yet been explained.

The Geneva Convention of July 6th, 1906, which replaced the earlier Convention of 1864, was signed on behalf of the German Government, and subsequently ratified by it. Nevertheless, the German authorities have obstinately refused to release the British medical personnel captured by them. Sir John Byers, in an interesting letter to the *Times* recently, gave cogent reasons why an interchange of medical prisoners of war ought to be arranged

without delay. But it must not be forgotten that no reasons are really needed for the prompt return to their own side of medical prisoners, since by international law medical men engaged in professional duties are immune from capture. Article 9 of the Geneva Convention of 1906 runs as follows:—

The personnel engaged exclusively in the collection, transport, and treatment of the wounded and the sick, as well as in the administration of medical units and establishments, and the chaplains attached to armies, shall be respected and protected in all circumstances. If they fall into the hands of the enemy they shall not be treated as prisoners of war.

Article 10 covers the case of British Red Cross surgeons, and begins as follows:—

The personnel of Voluntary Aid Societies duly recognised and authorised by their Government who may be employed in the medical units and establishments of armies is placed on the same footing as the personnel referred to in the preceding article, provided always that the first-mentioned personnel shall be subject to military law and regulations.

Article 12 provides for the return to their own side as soon as possible of recognised medical officers who have fallen into the hands of the enemy:—

The persons designated after they have fallen into the hands of the enemy shall continue to carry on their duties under his direction, and when their assistance is no longer indispensable they shall be sent back to their army or to their country at such time and by such route as may be compatible with military exigencies. They shall then take with them such effects, instruments, arms, and horses as are their private property.

Lastly, Article 13 should be quoted, for its terms seem, in many cases if not in all, to have been violated by the German authorities:—

The enemy shall secure to the persons mentioned in Article 9 while in his hands the same allowances and the same pay as are granted to the persons holding the same rank in his own army.

The extracts which we have given make it quite clear that the enemy to suit his own purposes has deliberately ignored the Convention to which he was a party. The question of exchanging military and Red Cross officers falling into the enemy's hands does not arise. The only ground for this repudiation of its duty which Germany could conceivably bring forward is Article 24:—

The provisions of the present Convention are only binding upon the contracting powers in the case of war between two or more of them. These provisions shall cease to be binding from the moment that one of the belligerent powers is not a party to the Convention.

With so many nations engaged in this world war, it may, for aught we know, be possible by some quibble to contend that some one or other of the States now at war omitted to sign or to ratify the 1906 Geneva Convention in the precise form laid down, and that Germany is thereby absolved from carrying out any duties which happen to be distasteful or inconvenient.

THE CASUALTY LIST.

For some weeks past the casualty lists have been lighter, and we have had to record no names of medical officers in the navy or army as killed, wounded, missing, or captured. H.M.S. *Viknor*, however, contained Surgeon Vernon Lickfold Matthews, R.N., among her officers, and it is assumed by the Admiralty that he lost his life with her. Lieutenant J. R. Waddy, R.A.M.C., was reported wounded on Jan. 31st.

TORPEDOING A HOSPITAL SHIP.

No doubt the German Admiralty will find some hair which can be split to excuse the murderous attack by a submarine upon the British hospital ship *Asturias* 15 miles off the Havre lightship on Tuesday last. But the fact remains that in defiance of humanity and the plain letter of international law a German torpedo was fired at a Red Cross vessel at 5 o'clock on a February afternoon, when it was too light for the attack to be made by error. Fortunately the attempt failed, but it will not be forgotten.

THE WAR AND THE SHORTAGE OF DOCTORS.—At the recent meeting of the Executive Committee of the General Medical Council, Sir Donald MacAlister gave some figures comparing the number of medical students now in attendance with the number at the beginning of the October session, 1913. The figures showed a reduction in the first year students of 49, second year 220, third year 256, fourth year 202, fifth year and higher 312. From these figures it is clear that for the next few years from 200 to 300 fewer medical men will qualify. This information has been communicated to the War Office, with a view to releasing for the completion of their curriculum the senior medical students enrolled in the Royal Army Medical Corps or serving with the Red Cross.

WOUNDED ALLIES RELIEF COMMITTEE.—This committee was established on the outbreak of war to coöperate with the Admiralty, the War Office, and the Red Cross Societies for the relief of wounded allies. Working in close coöperation with the British and Belgian Governments, it has arranged for 1800 wounded Belgians in hospitals in various parts of England and Scotland, and there are now about 60,000 of these men registered at the committee's bureau, of whom about 20,000 are in this country. The register is officially recognised by the Registrar General as the source of information concerning Belgian soldiers. The committee has arranged, and is now arranging, accommodation for convalescents on leaving hospital. It has become clear that the Wounded Allies Relief Committee is faced with a great undertaking and a great responsibility, which it is anxious to discharge.

The hospitals organised by Dr. Haden Guest at the Hotel Majestic in Paris, at Limoges, and at Nevers are doing valuable work in cordial relationship with the French authorities. The funds provided for general Red Cross purposes are only to a very small extent available for other than British wounded, and Belgian resources are, by the unhappy situation of that country, exhausted. In order to meet these great needs, which are bound to increase, the Wounded Allies Relief Committee appeals for a sum of £100,000, to be spent in the immediate work of the relief of the sick and wounded of our gallant allies. Remittances should be sent to the honorary treasurer, 217, Strand, W.C.

THE BELGIAN SOLDIERS' FUND.—This fund is appealing for regular weekly support in order to provide the Belgian soldiers at the front with a constant supply of food, comforts and warm clothing. The need of these men is very great; for their own people, most of whom are either in the hands of the Germans or refugees in foreign lands, are unable to send them the parcels from home that have meant much to the British Expeditionary Force. Food is soon used up, and clothing soon becomes unwearable from the conditions in the trenches. Therefore the Belgian Soldiers' Fund is appealing for weekly gifts of groceries, such as 1 lb. packets of coffee, biscuits, cocoa, lump sugar, rice, chocolate, macaroni, split peas, or one tin of meat, milk, jam, meat extract, &c., or one warm garment a week. The fund is also sending comforts of food and clothing to the Belgian military hospitals. Contributions in money or in kind and donations towards field kitchen comforts for providing hot meals to the men in the trenches will be gratefully received by the Secretary, the Belgian Soldiers' Fund, 19, James-street, Oxford-street, London, W.

DUBLIN CASTLE HOSPITAL.—This hospital, which is now ready for the reception of wounded soldiers, was thrown open during one afternoon last week for inspection by the public. The original intention was to

provide accommodation for 500 soldiers, but at the suggestion of the War Office the actual number of beds has been reduced to 250. There is little doubt that a much larger number can be put up should occasion require. The several rooms of the State apartments have been fitted up as wards for soldiers, notably the large rooms known as the Throne Room, the Gallery, and the Supper Room. They are lofty, bright, and cheerful rooms, well heated, though they have the defect of a northern aspect. There are no beds in St. Patrick's Hall, which is to be fitted as a recreation room. A number of smaller rooms, including those occupied by the King and Queen on their last visit to Ireland, have been specially fitted for officers. These rooms contain three or four beds each, and have a pleasant southern aspect. The theatre is a large circular room, which is fairly suitable for its purpose. Those in charge of the undertaking have made their arrangements with great expedition, and the hospital should be thoroughly efficient.

VACANCIES FOR MEDICAL OFFICERS.—Captain A. Mowat, commanding the Highland Mounted Brigade Field Ambulance, Royal Army Medical Corps, writes from the Drill Hall, Rose-street, Inverness, as follows: "Medical officers are urgently required for service with the above unit. There is also a vacancy for a medical officer for the 4th (Reserve) Cameron Highlanders. I shall be glad to give full information regarding pay and duties to anyone who applies to me at the above address."

In *Le Matin* of Jan. 17th appeared the following notice in reference to Mr. Bruce Burnside, who is now acting as surgeon in one of the French Red Cross hospitals: "The President of the French Republic has granted a silver medal of the second class for the saving of life to Dr. Bruce Burnside, a British subject, who distinguished himself by his courage and his devotion in saving, under particularly perilous circumstances, a child who had fallen into the river Gner, at Lannion, on the 29th of October, 1914."

JAPANESE RED CROSS SOCIETY.—On Jan. 29th Queen Alexandra received at Marlborough House the members of this society who have arrived in England for service and are now at Netley. The unit, which was presented to Her Majesty by the Earl of Onslow, included Dr. Jiro Suzuki, late Surgeon-General of the Imperial Japanese Navy, and Dr. Tsuneyshi Ashima. The personnel consists of 2 surgeons, 2 chief nurses, 20 nurses, a secretary, and an interpreter. They arrived at Liverpool on Jan. 22nd, when they were welcomed by Lord Onslow and Surgeon-General Sir B. Franklin on behalf of the British Red Cross Society, and by Mr. H. Bonar on behalf of the War Office. On Jan. 27th Lord Emmott, on behalf of the Government, entertained the four leading members of the party to dinner at the Carlton Hotel, Mr. F. Dyke Acland, Under Secretary for Foreign Affairs, presiding. Similar Japanese Red Cross ambulances have been despatched to France and Russia.

WAR GIFT FROM THE IMPERIAL COLLEGE.—On Feb. 2nd Surgeon-General Sir Alfred Keogh, K.C.B., Director-General of the Army Medical Department, was presented with a portable X ray apparatus of the War Office pattern by the staff and students of the Imperial College of Science and Technology. At the outbreak of war Sir Alfred Keogh, who is Rector of the College, was given leave by the governing body to act as Red Cross Commissioner in France, and he was subsequently called back to his former post at the War Office by Lord Kitchener. The X ray apparatus will be handed over to the No. 15 General Hospital for use at the front. Mr. A. H. D. Acland, chairman of the governors of the College, presided over a large gathering, and the presentation was made by Professor J. B. Farmer on behalf of the staff and Mr. R. L. Carr on behalf of the students.

Lieutenant-Colonel M. J. Whitty, R.A.M.C., who has held the post of senior medical officer of the Liverpool recruiting area for the past eight years, has been appointed medical officer of recruits in the Western Command.

It is announced that Sir Thomas Lipton's yacht *Erin*, with a British Red Cross party for the Balkans on board, have arrived safely at Brindisi.

Medical News.

UNIVERSITY OF CAMBRIDGE.—It is proposed by the council of the Senate to offer the following grace for approval by the Senate: "That on the recommendation of the State Medicine Syndicate the examination for the diploma in Psychological Medicine be not held in the present academical year."—The following medical degrees have been conferred:—

M.B. and B.C.—C. L. Gimblett, Caius.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A pathological meeting will be held to-day, Friday, Feb. 5th, in the society's rooms, West London Hospital. Specimens will be shown at 8 P.M. and the chair will be taken at 9 o'clock.

On Thursday evening, Jan. 28th, Mr. W. G. Martin, on his retirement from the post of head printer of THE LANCET after nearly 40 years of service, was entertained to dinner by past and present members of the staff, when a presentation was made to him by the Editor on behalf of some who have worked with him.

The Council of the University of Sheffield have appointed Mr. Arthur J. Hall, M.A., M.D. Cantab., F.R.C.P. Lond., to the post of Lecturer in Medicine.

THE PROFESSIONAL CLASSES WAR RELIEF COUNCIL.—The Lord Mayor of London has issued invitations to a public meeting to be held at the Egyptian Hall of the Mansion House on Tuesday, Feb. 16th, at 4 P.M., to consider how distress among the professional classes, attributable to the war, can best be prevented or relieved. The Archbishop of Canterbury and Sir Edward Clarke will address the meeting, and further information can be received from the honorary secretaries of the Council, 13, Prince's-gate, London, S.W.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

CROCKER, J. H., Medical Officer of Health of Richmond, Surrey, Captain. R.A.M.C. (Ter. S.S.), has been appointed Honorary Physician and Registrar to the Red Cross Hospital, Richmond, overflow to the 2nd London (City of London) General Hospital, Chelsea.
GUTHRIE, DOUGLAS, M.D., F.R.C.S. Edin., has been appointed Temporary Surgeon to the Edinburgh Ear and Throat Infirmary.
LEASK, HENRY L. G., M.D. Glasg., F.R.F.P.S. Glasg., has been appointed Surgeon to the Glasgow Eye Infirmary.
MCALLISTER, A. C., M.B., B.S. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed Obstetric Registrar to King's College Hospital, S.E.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

AYLESBURY, ROYAL BUCKINGHAMSHIRE HOSPITAL.—House Surgeon, unmarried. Salary £150 per annum, with board, washing, and lodging.
BENEDEN, KENT, NATIONAL SANATORIUM.—Medical Superintendent. Salary £350 per annum, with house.
BIRKENHEAD BOROUGH HOSPITAL.—Senior House Surgeon. Salary £120 per annum, with board and laundry.
BIRMINGHAM CITY MENTAL HOSPITAL, Rubery-hill.—Female Junior Assistant Medical Officer. Salary £260 per annum, with apartments, board, laundry, &c.
BLACKBURN AND EAST LANCASHIRE ROYAL INFIRMARY.—House Surgeons, Senior and Junior. Salaries £150 and £130 per annum, with board, residence, and laundry.
BOURNEMOUTH, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—Resident Medical Officer. Salary £300 per annum, with board, residence, and laundry.
BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £120 per annum, with board, residence, and laundry.
BRADFORD CITY.—Two positions on Staff of Medical Officer of Health in connexion with scheme of Child Welfare. Salary £350 per annum.
BRECKNOCK COUNTY AND BOROUGH INFIRMARY.—Resident House Surgeon. Salary £120 per annum, with apartments, board, attendance, laundry, &c.
BRIDGWATER HOSPITAL.—House Surgeon, unmarried. Salary at rate of £125 per annum, with board, lodging, and washing.
BRIGHTON, ROYAL SUSSEX COUNTY HOSPITAL.—House Physician. Salary £100 per annum, with apartments, board, and laundry. Also Junior House Surgeon and Assistant House Surgeon with charge of beds. Salaries £80 per annum, with apartments, board, and laundry.

BRISTOL EYE HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.
BRISTOL GENERAL HOSPITAL.—Senior House Surgeon. Salary at rate of £200 per annum, with board, residence, &c.
BRISTOL ROYAL INFIRMARY.—Throat, Nose, and Ear House Surgeon. Salary at rate of £120 per annum, with board, apartments, and laundry.
BURNLEY, VICTORIA HOSPITAL.—House Surgeon. Salary £135 per annum, with residence, board, and washing.
BURY INFIRMARY.—Junior House Surgeon. Salary £150 per annum, with board, residence, and washing.
CANCER HOSPITAL, Fulham-road, S.W.—House Surgeon for six months. Salary £100 per annum.
CANTERBURY, KENT COUNTY ASYLUM, Chatham.—Third Junior Assistant Medical Officer. Salary £250 per annum, with quarters, board, washing, &c.
CARLISLE, CUMBERLAND AND WESTMORLAND ASYLUM, Garlands.—Junior Assistant Medical Officer, unmarried. Salary £250 per annum, with board, lodging, and washing.
CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £75 per annum, with board, residence, and washing. Also Resident Medical Officer. Salary £200 per annum, with board, &c.
COLCHESTER, ROYAL EASTERN COUNTIES' INSTITUTION FOR IMBECILES AND THE FEEBLE-MINDED.—Female Medical Officer. Salary at rate of £200 per annum, with board, apartments, attendance, and washing.
COVENTRY, COVENTRY AND WARWICKSHIRE HOSPITAL.—House Physician. Salary £110 per annum, with rooms, board, washing, and attendance.
DERBYSHIRE COUNTY COUNCIL.—Tuberculosis Dispensary Officers. Salary £400 per annum.
DOMESTIC SERVANTS' INSURANCE SOCIETY.—Medical Referee and Adviser one hour per day. Salary 150 guineas per annum.
DUDLEY, GUEST HOSPITAL.—Senior Resident Medical Officer. Also Assistant House Surgeon. Salary £150 and £120 per annum respectively, with board, residence, attendance, and washing.
DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—Female Resident House Surgeon.
EAST LONDON HOSPITAL FOR CHILDREN, Shadwell.—Resident Medical Officer, House Physician, and House Surgeon.
ECCLES AND PATRICKROFT HOSPITAL.—House Surgeon, unmarried. Salary £70 per annum, with board, lodging, and washing.
EXETER, ROYAL DEVON AND EXETER HOSPITAL.—Senior House Surgeon for 12 months. Also House Physician and Assistant House Surgeon for six months. Salary at rate of £250 per annum for senior post and £150 for junior posts, with board, apartments, and washing.
GLOUCESTER COUNTY ASYLUM, Barnwood, near Gloucester.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, lodging, laundry, and attendance.
HACKNEY UNION INFIRMARY, High-street, Homerton, N.E.—Junior Assistant Medical Officer. Salary £250 per annum, with rations, apartments, and attendance.
HALIFAX ROYAL INFIRMARY.—Second and Third House Surgeons, unmarried. Salary £120 and £100 per annum respectively, with residence, board, and washing.
HAMMERSMITH INFIRMARY, Ducane-road, Wormwood Scrubs, W.—Second Assistant Medical Officer. Salary £130 per annum, with board, lodging, washing, and attendance.
HOSPITAL FOR DISEASES OF THE SKIN, Stamford-street, Blackfriars, S.E.—Clinical Assistant.
HUDDERSFIELD, COUNTY BOROUGH.—Medical Inspector of School Children. Salary £300 per annum.
HULL, VICTORIA CHILDREN'S HOSPITAL, Park-street.—Female House Surgeon and Female Assistant House Surgeon. Salary £60 and £50 per annum respectively, with board and laundry. Or Male Resident House Surgeon. Salary £60 per annum, with board and laundry.
KENSINGTON TUBERCULOSIS DISPENSARY, 119, Ladbroke-grove, W.—Temporary Medical Officer. Salary at rate of £500 per annum.
LEEDS HOSPITAL FOR WOMEN AND CHILDREN.—House Surgeon for six months. Salary at rate of £50 per annum.
LEEDS UNIVERSITY.—Demonstrator of Bacteriology. Salary £250 per annum.
LEICESTER EDUCATION COMMITTEE.—Temporary Assistant Medical Officer. Salary £300 per annum.
LIVERPOOL, COUNTY ASYLUM, Rainhill.—Locum Tenens Assistant Medical Officer.
LIVERPOOL INFIRMARY FOR CHILDREN.—Two Resident House Physicians for six months. Salary £30 each, with board and lodging.
LONDON HOMOEOPATHIC HOSPITAL, Great Ormond-street and Queen-square, Bloomsbury, W.C.—Surgeon for Diseases of the Eye.
LONDON LOCK HOSPITAL, Dean-street, Soho, W.—House Surgeon for six months. Salary at rate of £100 per annum. Also Honorary Anaesthetist once a week.
MANCHESTER CHILDREN'S HOSPITAL, Pendlebury.—Visiting Surgeon. Salary £100 per annum.
MANCHESTER CORPORATION.—Two Assistant Tuberculosis Medical Officers. Salary £350 each per annum.
MANCHESTER, COUNTY ASYLUM, Prestwich.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, attendance, and washing.
MANCHESTER EDUCATION COMMITTEE.—Two Assistant School Medical Officers. Salary £300 per annum.
MANCHESTER, HULME DISPENSARY, Dale-street, Stretford-road.—House Surgeon. Salary £180 per annum, with apartments, attendance, coal, and gas.
MANCHESTER, MONSIEUR FEVER HOSPITAL.—Second and Third Medical Assistants. Salary £175 and £150 per annum respectively, with board, lodgings, and washing.
MANCHESTER, ST. MARY'S HOSPITALS FOR WOMEN AND CHILDREN.—Resident Surgical Officer at High-street Hospital. Salary £90 per annum, with board and residence. Also House Surgeon for three or six months. Salary at rate of £70 per annum, with board and residence. Also House Surgeon at Whitworth-street West Hospital for three or six months. Salary at rate of £70 per annum, with board and residence.
MIDDLEBROUGH COUNTY BOROUGH.—Temporary Chief Tuberculosis Medical Officer. Salary £500 per annum.
MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Junior House Surgeon for six months. Salary £25 per annum, with board, residence, and laundry.

Notes, Short Comments, and Answers to Correspondents.

THE ARMY MEDICAL SERVICE: LOOKING BACKWARD.

A CORRESPONDENT writes: The first definite information of medical men in the battlefield occurs in the reign of Henry V., when Nicholas Colnet, as physician, and Thomas Morestede, as surgeon, accompanied the King in his expedition into France. The pay of each of these officers was 1s. a day and a bodyguard of three archers. As a security for this payment Colnet and Morestede were allowed to take with them certain valuable jewels belonging to the King. Morestede took with him 12 assistants, who each received 6d. a day. He was also supplied by the King before starting with a sum of money to provide a suitable equipment. Further, he was provided with a "chariot, two waggons, and two sumpter horses." Morestede was present at the battle of Agincourt, where he and his assistants must have found abundant scope for their energies, for the casualties were enormous. The casualties on the English side are not known, but the mortality among the French is said to have exceeded 11,000. Morestede's medical colleague must also have had his hands full, for the English troops suffered badly from dysentery. The war over, Morestede returned to London and took an active part in the Surgeons' Guild. He became wealthy and added an aisle to St. Olave's Church, Jewry, where he was buried.

THE DEARER LOAF.

To the Editor of THE LANCET.

SIR,—As you so truly say in the leading article in your issue of Jan. 30th that nourishing bread is of the utmost importance to "the extreme poor, often limited, sadly enough, to bread with butter or jam," I venture to direct attention to the advantages of wholemeal ground to a uniform fineness, so that the digestive juices can surround the particles and extract their nutriment. The Bread and Food Reform League has emphasised the importance of this subject for over 30 years, and has also advocated that, when finely ground wholemeal and wheatmeal (a grade from which a little of the coarse bran has been removed) cannot be assimilated, it is advisable to encourage the use of household flour containing the maximum nutriment of the wheat grain that can be obtained with a smaller amount of indigestible woody fibre. The league especially advises the retention of the "germ" and the strong gluten, found in flours commercially designated "patents," which are now abstracted and used for expensive breads.

Recent scientific investigations prove that serious disease is produced by minute alterations in foodstuffs, and that the vitamins found in wholemeal, wheatmeal, and old-fashioned household flour, but removed from fine white flour, are most important elements of nutrition when bread forms the principal food. As practical experience shows the beneficial results secured by the use of these breads when genuine I venture to hope that your readers will most kindly encourage their adoption and thus help to promote the healthy nutrition of the people.

I am, Sir, yours faithfully,

MAY YATES,
Honorary Secretary, Bread and Food
Reform League.

5, Clement's Inn, London, W.C., Feb. 1st, 1915.

THE CENTRAL COMMITTEE FOR NATIONAL PATRIOTIC ORGANISATIONS.

THE task laid out for itself by this committee seems in every way worthy of vigorous support. It is that of stimulating and instructing public opinion throughout the country in respect of the causes and objects of the war, of arousing the nation to a sense of its danger, and keeping it alive, for the great driving power of public opinion, upon which ultimately the end of the war will depend, must not be left to shift with the temporary dominance of various temperaments or the changing fortunes of war. Any weakening or wavering or a patched-up truce would only expose our children under far more disadvantageous circumstances to the rule and methods of a ruthless militarism that is a standing menace to civilisation, democracy, and liberty throughout the world. Another portion of the committee's work consists in translating into the languages of the respective neutral countries the full evidence on which the Allied case rests and taking measures for its circulation therein. The president of the committee is Mr. Asquith, and the

NEWPORT (MON.), ROYAL GWENT HOSPITAL.—Resident Medical Officer. Salary for first six months at rate of £100 per annum, second six months £125, and third six months £150, with board, residence, and laundry.

NORTHAMPTON COUNTY ASYLUM.—Second Assistant Medical Officer. Salary £250 per annum, with board, &c.

NOTTINGHAM GENERAL HOSPITAL.—Senior House Physician. Salary £120 per annum, with board, residence, and laundry. Also Assistant House Physician for six months. Salary at rate of £100 per annum, with board, residence, and laundry.

Births, Marriages, and Deaths.

BIRTHS.

CORBETT.—On Jan. 27th, at Blackwell, near Bristol, the wife of Captain D. M. Corbett, R.A.M.C., of a daughter.

HAY.—On Jan. 23th, at 20, St. James's-place, S.W., the wife of Kenneth R. Hay, M.B., of a son.

DEATHS.

DOUGHTY.—On Jan. 23th, at Woodchurch, Kent, William Cape Doughty, L.R.C.P. & S., after a short illness, aged 31 years.

MORISON.—On Jan. 28th, at the residence of his brother, 14, Upper Berkeley-street, W., Basil Gordon Morison, M.D., aged 60 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

vice-presidents are Lord Rosebery and Mr. A. J. Balfour. Contributions or offers of other assistance should be made to the secretary, the Central Committee, Canadian Pacific Building, 62, Charing Cross, W.C., from whom also further information can be obtained.

POPULAR MEDICINE IN GERMANY.

To the Editor of THE LANCET.

SIR,—In reference to your remarks on Father Kneipp's book, published under this heading last week, I may call the attention of your readers to Rehm's "Allerlei," published in Ulm in 1806. Rehm was a Prussian and Polizeidirektor, and his book therefore is marked by a Protestant rationality, in strange contrast to the Rev. Father's romantic note. It is interesting to compare his work, however, with such books as the Scottish "Tippermalluch's Receipts" and the English "One Thousand Notable Things," which were popular domestic medicine books of the latter end of the eighteenth century. Rehm, it must be confessed, contains very little quaint folklore as do Tippermalluch and the English chap-book. There is nothing in his pages to remind one of the medicinal stones mentioned in the Scandinavian mythology. Nor do cannibalism and charms here appear. But the pharmacopœia of Rehm is evidently traditional. Against the tape-worm he proceeds as he might against a dragon. An immense tripartite dose is given to the patient. It comes traditionally from Leibnitz Vogler, "of blessed memory." The worm is expelled *seriatim* at intervals of an hour or so, and the first dose is composed of quicksilver and pounded shells. A paste made of the yolk of an egg mixed with pounded sal ammoniac is recommended as a remedy for cataract. Oil of spurry (*spargula*) is stated to be a sovran remedy for hæmorrhage of the lungs, and it is noted that cattle feed and grow fat upon it, while it increases the wool-bearing capacities of sheep. Certain harmless directions are given for the treatment of epilepsy, and it is noted that the disease is popularly supposed to reside in the thumbs, whence the vulgar are always anxious to keep the patient's thumbs from being bent in upon the palms of his hands. A barbaric way of keeping fish fresh in winter is to pack them in snow, which benumbs but does not kill them—at least, this is Rehm's experience. Curious side-lights such as this are thrown on the life of the times. For instance, a story is told of the shooting of a mad dog, the fat of which was at once sold to a druggist for some reason or other. The deaths of dogs and even human beings are often attributed to the bite of flies that have escaped from fly-papers. Frost-bite is frequently mentioned, and it is cured by medication rather than by the application of snow. The juice of potatoes is used as a substitute for soap, and bread made of the same tuber is described and lauded as an article of diet.

Reading this book, we feel that we are in a primitive kindly world of peasants, scarcely in a savage one, still less in one that would adumbrate the latter-day Prussian.

I am, Sir, yours faithfully,

Feb. 2nd, 1915.

BOOKWORM.

A SWEDISH REMEDY FOR FROST-BITE.

WE have received from Mr. Edward Edwin, of 39, Beauchamp-road, Lavender Hill, London, S.W., samples of an ointment called "Vetterin," which he states has been used for years with the greatest success in Sweden for the treatment of frost-bite. Mr. Edwin quotes a number of letters from Swedish medical men which speak so confidently about the merits of this preparation as to make it well worthy a trial elsewhere than in Sweden.

THE LESION IN TETANUS.

To the Editor of THE LANCET.

SIR,—I have read in THE LANCET of Jan. 2nd, p. 17, a report of the successful treatment of tetanus in a case having the remarkably short incubative period of two days. There is nothing in the report showing at all conclusively that the condition arose from abrasion of the hip, protected as it must have been by clothing; and as the percentage of recovery in tetanus is increased as the incubation period is lengthened—recovery in five-day incubation cases being rare even under massive doses of antitetanic serum—is it not well to assume the existence of some trivial lesion, oral, intestinal, &c., acting as a nidus for the infection, rather than accept a recent, absolutely superficial injury as the field of ultra virulent infection?

I am, Sir, yours faithfully,

THOS. B. ROGERS, D.V.S.

Woodbury, N.J., Jan. 17th, 1915.

Cheval.—The very small average of six miles a day would not appear to justify, financially speaking, the keeping of a car, unless our correspondent has a place attached to his house where he can keep it, and has the intention of extending the sphere of his operations. If he

will tell us the cost of his present system of hiring a brougham, whether he would drive a car himself, and where he would keep it, we shall be better able to advise him. He could probably get a booklet on the subject of the running cost from Messrs. De Dion Bouton, 10, Great Marlborough-street, London, W.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Papers:—Dr. D. H. Scott: *Lepidostrobos* Kentuckyensis, formerly *Lepidostrobos* Fischeri. Scott and Jeffrey—A Correction.—Mr. T. Lewis and Mr. M. A. Rothschild: The Excitatory Process in the Dog's Heart. Part II., The Ventricles (communicated by Prof. E. H. Starling).—Mr. A. J. Walton: On the Variation in the Growth of Mammalian Tissue in Vitro according to the Age of the Animal (communicated by Prof. W. Bulloch).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

FRIDAY.

CLINICAL SECTION (Hon. Secretaries—Thomas H. Kellock, David Forsyth): at 8 p.m.

Cases:

Mr. H. Morriston Davies: (1) Bronchiectasis treated by Ligation of the Branch of the Pulmonary Artery; (2) Mediastinal Teratoma—Result of Operations on; (3) Osteitis Fibrosa Cystica of the Femur.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 p.m., Discussion on Gunshot Wounds of the Head (introduced by Sir Victor Horsley). Followed by Sir David Ferrier, Mr. R. Warren, Mr. W. H. Jessop, Mr. L. B. Rawling, and others.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, Lecture Theatre of the Society, 17, Bloomsbury-square, W.C.

TUESDAY.—8 p.m., Communications from the Society's Research Laboratories:—Prof. H. L. Smith: Acetylsalicylic Acid.—Prof. H. G. Greenish and Mr. A. E. Beesley: Discolouration of Sodium Salicylate in Solution by Alkalines.

HUNTERIAN SOCIETY, Barbers' Hall, Monkwell-street, E.C.

WEDNESDAY.—9 p.m., Annual Oration:—Dr. H. R. Andrews: William Hunter's Work on Midwifery.

SOUTH-WEST LONDON MEDICAL SOCIETY, Bolingbroke Hospital, Wandsworth Common, S.W.

WEDNESDAY.—9 p.m., Dr. A. F. Hertz: Flatulence.

CHILD STUDY SOCIETY LONDON, Royal Sanitary Institute, 90, Buckingham Palace-road, S.W.

THURSDAY.—6 p.m., Lecture:—Dr. C. W. Kimmins: With the British Association in Australia.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 a.m., Dr. Simson: Diseases of Women. 10.30 a.m., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—10 a.m., Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 a.m., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 11 a.m., Mr. Souttar: Demonstration of Minor Operations. 12 noon, Lecture:—Mr. Souttar: Abdominal Diagnosis. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 a.m., Dr. Bernstein: Bacterial Therapy Department. 12 noon, Lecture: Dr. G. Stewart: Neurological Cases. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 a.m., Dr. Simson: Gynaecological Operations. 10.30 a.m., Surgical Registrar: Demonstration of Cases in Wards. 12.15 p.m., Lecture:—Dr. Bernstein: Applied Pathology. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 a.m., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 12 noon, Lecture:—Mr. Souttar: Surgical Anatomy of the Abdomen. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 a.m., Surgical Out-patient (Mr. E. Gillespie). 2.30 p.m., Medical Out-patient (Dr. T. R. Whipham); Gynaecological (Dr. J. B. Banister). 3 p.m., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. Howell Evans); Nose, Throat, and Ear (Mr. H. D. Gillies). X Rays and Electrical Methods (Dr. Metcalfe). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whiphram); Skin (Dr. G. N. Meachen); Eye (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynaecological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson); X Rays and Electrical Methods (Dr. Metcalfe); 4.30 P.M., Clinical Demonstration:—Dr. R. M. Leslie: Selected Medical Cases.

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden-square, W.
MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M., Clinical Lecture.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.
TUESDAY.—4 P.M., Dr. J. L. Bunch: Some Common Skin Diseases.
THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Fungus Diseases of Skin and Hair.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.
TUESDAY.—3 P.M., Prof. C. S. Sherrington: Muscle in the Service of Nerve. (Lecture III.)
THURSDAY.—3 P.M., Dr. P. C. Mitchell: Zoological Studies: War and Evolution—Nations as Species. (Lecture I.)
FRIDAY.—9 P.M., Dr. W. S. Bruce: Recent Advances in Oceanography.

ROYAL SANITARY INSTITUTE, 90, Buckingham Palace-road, S.W.
TUESDAY.—7.30 P.M., Discussion on Tall versus Short Men for the Army (opened by Dr. M. S. Pembrey).

MANCHESTER HOSPITALS POST-GRADUATE CLINICS.
THURSDAY.—ANCOATS HOSPITAL, Mill-street.—4.30 P.M., Dr. A. Renshaw: Vaccine Treatment of Respiratory Diseases.
For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1914 were given in THE LANCET of Dec. 26th, 1914.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1914 are now ready. Bound in cloth, gilt lettered, price 16s., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents

(with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.			TO THE COLONIES AND ABROAD.		
One Year	...	£1 1 0	One Year	...	£1 5 0
Six Months	...	0 12 6	Six Months	...	0 14 0
Three Months	...	0 6 6	Three Months	...	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

Remarks

PUERPERAL ECLAMPSIA.

Being the Introduction to a Discussion at the Midland Medical Society on Jan. 27th, 1915.

By C. E. PURSLOW, M.D. LOND.,
M.R.C.P. LOND.,

HONORARY OBSTETRIC OFFICER, QUEEN'S HOSPITAL, BIRMINGHAM;
LECTURER ON MIDWIFERY AND DISEASES OF WOMEN, UNIVERSITY OF BIRMINGHAM; CONSULTING SURGEON,
BIRMINGHAM MATERNITY HOSPITAL AND
LYING-IN CHARITY.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—For the purposes of this discussion I will divide the subject into the following sections: I., Prophylactic Treatment; II., Treatment of the Fits and of the Toxæmia; III., Obstetrical Treatment.

I.—PROPHYLACTIC TREATMENT.

As regards prophylactic treatment there can be no doubt that in many cases in which the disease is threatened it can be warded off by appropriate means, and success depends on an early recognition of symptoms of the pre-eclamptic state; these are numerous, but I should say that the most constant and important are: albuminuria, persistent headache, and oedema. Other symptoms may be disturbances of vision and hearing and vomiting. One prodromal symptom which is not common, but which when it occurs is, in my opinion, of most unfavourable prognostic import, is severe epigastric pain. The albuminuria associated with eclampsia, in which there is usually a large amount of albumin present, is practically confined to the later half of pregnancy, cases of eclampsia before then being rare. Pronounced albuminuria in the later months is a dangerous complication for both mother and child, and the danger of the condition is greatly increased by the fact that it is so often unrecognised and untreated until the sudden onset of a convulsion calls attention to the case.

It should be made a rule to examine the urine of every pregnant woman in the latter half of pregnancy, and the examination should be repeated at intervals, shorter as full term approaches; if this rule were adhered to the death-rate from eclampsia would be greatly reduced. It should always be borne in mind that a haze of albumin may be due to mixture with vaginal discharge, so that if albumin is present in the specimen passed by a patient we should never base a diagnosis or treatment on that, but should examine a catheter specimen. If, on the other hand, there is no albumin in the specimen voided by the patient it will not be necessary to pass a catheter. If albumin is present a microscopical examination and an estimation of urea are advisable. Statistics show that this disease is more likely to occur in primiparae, and in my experience it has seemed that its occurrence was more to be feared in well-developed women who had been in the habit of taking a large amount of exercise and eating much solid food.

When albumin is found in considerable quantity in the urine of women in the later months the case should be taken in hand at once. In the first place the patient should be confined strictly to bed, and it is a very good plan to commence the treatment by giving nothing whatever but water for the first 48 hours. Afterwards milk, well diluted, may be given, and the diet should be limited to that until there is distinct improvement in the secretory function of the kidneys. Free purgation is essential,
No. 4772.

and for this purpose 30 gr. of pulv. jalapæ may be given, or sodii sulph. $\mathfrak{z}\text{i}$., in water $\mathfrak{z}\text{ii}$., every two hours, until free purgation is produced. Rectal injections of normal saline may be given after the bowels have been well emptied, or saline may be given sub cute. If in spite of this treatment the renal secretion does not improve, or if prodromata of eclampsia come on, the difficult question of induction of premature labour presents itself. On the whole, I am inclined to advise that labour should not be induced. I have seen some most satisfactory cases in which the treatment already set out has been followed by spontaneous delivery without the occurrence of eclampsia, even when the patient has seemed to be on the verge of an attack.

II.—TREATMENT OF THE FITS AND OF THE TOXÆMIA.

The practitioner is generally sent for as soon as a fit has occurred, and in some cases it will happen that there will have been no prophylactic treatment because the patient had not been under medical care, and neither she nor her friends will have suspected that anything was wrong until they are alarmed by the occurrence of a fit. The patient should be at once put to bed in a darkened room and preserved from all external causes of irritation as far as possible. An efficient nurse should be obtained, and she should be instructed that if another fit comes on the patient should be watched carefully to see that no harm befall her, as by suffocating in the bedclothes or falling out of bed. During the fit a piece of wood should be placed between the teeth to prevent the tongue being badly bitten. It is a good plan to place one side of the bed against the wall, as the nurse can then more easily control the patient. During the coma which follows a fit the head should be brought to the edge of the bed and turned well over on one side so as to allow saliva to escape and prevent it entering the trachea.

I may say here I am sure that those who have had cases of this kind among the poor will have appreciated the advantages of obtaining admission for them to the Maternity Hospital, which, if only for the treatment of this disease, has proved a most valuable addition to the charitable institutions of the city. If the patient is able to swallow she may be given water, but no food, not even milk, should be given. A quickly acting aperient may be given, and one of the best is croton oil m ii ., made up with powdered sugar and placed on the tongue; in addition a copious enema of soap and water may be given, and when this has acted a further rectal injection may be slowly given of 4 ounces of water containing 2 ounces of sulphate of magnesia. If the apparatus is at hand it is also well to wash out the stomach. Poultices to the loin probably encourage action of the kidneys, and at all events can do no harm. I am not in favour of hot-air baths. One of the few methods, in addition to purgation, upon which almost all writers are agreed is the administration of subcutaneous or intravenous injections of saline; chloride of sodium $\mathfrak{z}\text{i}$. to the pint, or, better still, $\mathfrak{z}\text{i}$. each of chloride and acetate of sodium; the salt may be obtained ready for use in glass containers, and Horrocks's small saline infusion apparatus is in my opinion the best and simplest, and should be carried in every midwifery bag.

Before proceeding to discuss the obstetrical aspect of the question I will refer briefly to some of the numerous other methods which have been advocated for dealing with the fits and toxæmia,

and I hope that we may hear their virtues or faults described in the discussion.

Chloroform.—If any operative interference is contemplated, even such a small procedure as puncture of the membranes, chloroform should be given, but I am entirely opposed to the method so frequently adopted of attempting to control the convulsions by its continuous or intermittent administration.

Morphia.—This treatment has been extensively advocated of late years; it is given by hypodermic injection in an initial dose of $\frac{1}{2}$ grain and subsequent doses of $\frac{1}{4}$ grain until a total amount of 2 grains has been reached. I have tried it, but have not been convinced of its advantages, and have not used it lately, and I would say the same of *venesection*.

Thyroid extract in doses of 30 to 40 grains has been suggested by Nicholson, of Edinburgh, who reports good results from its use.

Nitro-glycerine in subcutaneous injection up to 5 minims has been tried with successful results by Dr. McCarthy, one of our past presidents, and I have no doubt some of those present may be able to speak of its use.

Veratrum viride has been extensively used in America, and recently Haultain, of Edinburgh, has brought forward several successful results from the hypodermic injection of veratrine. This remedy is said to be particularly indicated in cases of high pulse tension.

Pilocarpine has been extensively used, but on account of its tendency to increase bronchial secretion it is, in my opinion, a dangerous drug.

Oxygen inhalation in cases where cyanosis is a marked symptom would be highly desirable.

Cold baths are said to be useful in cases in which hyperpyrexia is a marked symptom; this is a not infrequent complication of eclampsia, and is one of bad prognostic import.

Decapsulation of the kidneys and *lumbar puncture* have both been advocated and practised, but only to a limited extent, and apparently without any striking success.

III.—OBSTETRICAL TREATMENT.

There have been many differences of opinion revealed in the methods of treatment we have already been considering, but when we enter on the consideration of the obstetrical treatment we might describe the authorities as being divided into two hostile camps, their actions depending in a large degree on the views they hold as to the causation of eclampsia. The one, which I may call the Rotunda school, believes that the toxin is elaborated from the food taken in by the mother owing to some faults in her metabolism. The other, or what I may call the German school, considers it to be due to the foetus, and has advanced the theory recently that the symptoms are due to placental albumin finding its way into the maternal blood-stream in quantities greater than can be dealt with at the time by the antibodies which are elaborated to deal with it. It is on the presence of these antibodies in the maternal blood that Abderhalden's serum test for the diagnosis of pregnancy is based. Those holding the first view advise little or no interference with the process of labour; while to those holding the second no methods are too radical—induction of labour, accouchement forcé, vaginal and abdominal Cæsarean section being each advised in particular cases.

Personally, if labour has started and can be terminated quickly under an anæsthetic by forceps I

should not hesitate to interfere, but the difficult cases are those in which severe eclampsia is in progress, fit succeeding fit, with no lucid interval, and in which there is no sign of labour, the os remaining closed and the cervix not taken up.

I have treated cases of this kind on both the expectant plan and on the lines of active interference. In an article on the treatment of eclampsia which I wrote three years ago for Latham and English's "System of Treatment" I stated that, on the whole, I thought that the results from interference were slightly better than those obtained when no steps were taken to evacuate the uterus; since then, as a result of further experience of the policy of non-interference, I am inclined to modify those views, and the results in the last case which was under my care were so striking that I may perhaps be pardoned for quoting it.

The patient was admitted to the Queen's Hospital, Birmingham, on Dec. 1st last on the recommendation of Mr. Sydney E. Price, of Dudley Port. She was a primipara, 28 years of age, well developed, and in the seventh month of pregnancy; she had been having fits for about 48 hours and had had more than 80 altogether.

On admission the patient was œdematous, comatose, and her heart-beat was 160 and the pulse uncountable at the wrist. She was given an enema and subsequently a rectal injection of $\frac{3}{4}$ ii. magnes. sulph. in water. Two pints of saline were then injected slowly into the submammary region. She was admitted at 1 A.M. No obstetrical treatment was adopted, and at 7.30 A.M. she delivered herself of a stillborn male child by the breech; the placenta did not come away and had to be removed by hand. During the day she had another subcutaneous saline and mag. sulph. injection by rectum every six hours. She remained completely comatose for 36 hours, then slowly recovered consciousness and began to pass urine, and left the hospital well on the ninth day after admission.

This case was a striking illustration of the success of this line of treatment, which was carried out entirely by Miss Hemingway, my house surgeon, to whose persevering and careful attention the patient largely owes her life. If we decide on an active line we have a large number of measures open to us, and I will briefly consider these. They are puncture of membranes; bougies; packing the cervix and vagina; tents; rubber dilating bags; digital dilatation or dilatation by Bossi's dilators, followed by version or forceps; deep incision of the cervix, including the so-called vaginal Cæsarean section; and abdominal Cæsarean section.

Puncture of the membranes can be done with little disturbance of the patient, and is a harmless proceeding; it rapidly diminishes intrauterine tension, but as a means of inducing labour it is very uncertain in the time it takes; if done, every anti-septic precaution should be taken.

As regards the other methods, I would say emphatically of the slow ones (under which I include bougies, tents, packing of the cervix and vagina, and rubber dilating bags, including that of Champetier de Ribes) that they are contra-indicated in the treatment of eclampsia, and if there is one thing about which I am convinced in this question it is that interference, if decided upon, should be by rapid methods under anæsthesia, and I would select dilatation by Bossi's dilator or vaginal or abdominal Cæsarean section. I think that, on the whole, for this class of case the form of active treatment likely to be least prejudicial would be abdominal Cæsarean section, but I feel convinced that if a good trial be given to the milder methods it will be found that the results will be better than those obtained by the most heroic operative procedures.

EXPERIMENTAL PURPURA.

(Second Communication.)

BY J. C. G. LEDINGHAM, M.B., D.Sc. ABERD.,
CHIEF BACTERIOLOGIST, LISTER INSTITUTE;
ANDS. P. BEDSON, M.D., M.Sc. DURH.,
LATE BRITISH MEDICAL ASSOCIATION RESEARCH SCHOLAR,
LISTER INSTITUTE.

In a preliminary communication by one of us (Ledingham¹) to this journal on June 13th, 1914, the production of purpura hæmorrhagica in guinea-pigs, after inoculation with an antiserum prepared by immunising rabbits with guinea-pig blood plates, was placed on record. The present paper deals mainly with conjoint work carried out in June and July of last year, together with additional experimental data since obtained by one of us (L.) in the absence of the other (B.) on military service. The blood changes in guinea-pigs inoculated with anti-plate serum have been followed out in detail, and we propose in the first place to submit data on this point. A description will follow of experimental purpura in the rabbit and rat induced by inoculation with their respective anti-plate sera.

Blood Changes in Guinea-pigs after Inoculation with Anti-guinea-pig-plate Serum.

Notes on technique.—The blood plates were counted in a Thoma-Zeiss chamber, the blood from the ear being received into citrate solution containing brilliant cresyl blue which showed up the blood plates very clearly. The figures for the plate content per c.mm. obtained by this method in a series of normal guinea-pigs were as follows: 856,000, 752,000, 340,000, 640,000, 672,000, 688,000, 590,000, 696,000, 664,000, 592,000 (the latter four obtained from the same animal on four successive days), 592,000, and 584,000. The average of nine animals works out about 638,000 per c.mm. The hæmoglobin was estimated by Haldane's instrument. Attempts were also made to obtain coagulation times, but as we have not satisfied ourselves that the methods employed yield reliable results, at least so far as the guinea-pig is concerned, we refrain at present from alluding to them. The statement in the preliminary communication that the clotting is delayed rested entirely on observations of the bleeding time after puncture. Prolongation of the bleeding-time after puncture of the ear vein is a very marked feature in experimental guinea-pig purpura (as Duke asserts to be the case in human purpura), but this function may prove to have no direct relation to the coagulation time as ordinarily understood and calculated.

The three animals, B 3, B 4, and B 5, whose blood changes, &c., have been followed daily, received each one dose of anti-plate serum (1.5 c.c.) subcutaneously immediately after the control normal samples had been taken. The animals were purposely chosen of large size (over 400 gm.), so that a lengthy observation period would be available before the fatal conclusion (or possibly recovery) resulted. It had previously been determined that in animals of 250 gm. a dose of 1 c.c. of a particular batch of anti-plate serum had produced death in three, four, or five days with typical purpuric lesions. The data obtained from these three large animals, together with notes of the general condition, are found in Table I. (see p. 312).

¹Ledingham (1914): The Experimental Production of Purpura in Animals, &c., THE LANCET, vol. I., 1914, p. 1673.

Remarks on Table I.—It will be observed from the table that two of the animals died in 4 and 8 days respectively, while the third animal (B 3), whose initial weight was 450 gm., made a complete recovery after exhibition of purpuric skin lesions. On July 14th—i.e., 36 days after the first dose—it received a second dose of 2 c.c. of the serum. The reaction to this second dose was very slight, the blood plates only, showing a marked fall, while the purpuric skin spots were few. It is impossible here to analyse the blood changes in detail, but certain points deserve notice. 1. The total leucocyte count is not appreciably affected, though there is a distinct tendency to relative lymphocytosis (see the column of differential counts). 2. The blood plates are the elements which suffer the earliest and promptest reduction. Except in the case of B 5, which showed an abnormally low initial plate content, the plates fell to one-sixth to one-tenth of their initial figure. In animal B 3, which recovered, the rapid regeneration of red cells and hæmoglobin is well seen. In the last two columns data are appended with reference to the presence of hæm-agglutination in the shed blood, the minute changes in the red cells, and the general condition of the animals.

Post-mortem appearances of the above three animals. B 3.—Killed for examination on July 18th. A few skin hæmorrhages present at site of last inoculation. A few groups of faded punctiform hæmorrhages in stomach wall. No petechiæ on heart or lungs. Lymph glands not of hæmolymp character. Urine not stained with hæmoglobin.

B 4.—Dead June 16th. This animal had shown numerous skin hæmorrhages during the early days following inoculation of the serum. At necropsy these had faded and skin hæmorrhages were found only in the neighbourhood of the inoculation site. The red colour of the lymph glands was disappearing. Several hæmorrhages in the lungs and very numerous petechiæ in intestine. Stomach mucosa showed two round patches—one about the size of a sixpence, the other half that size—studded with small punctiform hæmorrhages. There was no ulceration. Liver yellowish. Spleen large, dark red, and friable. Kidneys and adrenals apparently normal.

B 5.—Dead June 12th. Numerous hæmorrhages at site of inoculation and a few scattered about elsewhere. Only a few lymph glands show the hæmolymp change. No hæmorrhages in intestine. Liver pale and yellowish. Spleen greatly enlarged and friable. Urine blood-stained. A few small hæmorrhages in testicles. *Both eyes show cataract.*

Blood Changes in Smaller Animals.

To complete this part of the subject tables are also appended showing the variations in the red cells, blood plates, hæmoglobin, &c., in three guinea-pigs of less weight. Each was inoculated on June 30th, 1914, with 1 c.c. of anti-plate serum subcutaneously. (See Tables II. A, II. B, and II. C).

TABLE II.A.—Guinea-pig 8.

Date.	Red cells.	Plates.	Hb.	Weight.
June 30th*	5,744,000	640,000	96%	240 gm.
July 1st	5,944,000	512,000	94%	220 "
" 2nd	5,130,000	320,000	80%	210 "
" 3rd	664,000	98,000	—	200 "

Death between 1 and 2 p.m. on July 3rd.

* Received 1 c.c. anti-plate serum subcutaneously.

Notes on blood picture and general condition.—July 1st: Blood picture normal except for one or two red cells showing polychromatophilia. Well-marked hæmagglutination. Pig lively. Distinct infiltrate over abdomen. July 2nd: Some irregularity in shape of red cells. Megalocytes of medium size, fairly numerous, mostly showing polychromatophilia. Some red cell shadows. Pig seems ill. Infiltrate softening. Some skin hæmorrhages. Gums of fairly good colour. July 3rd: Hæmagglutination of shed blood most pronounced. Great irregularity in size of red cells. Megalocytes showing

Death between 1 and 2 P.M. on July 3rd.

* At 5 P.M. received 1 c.c. anti-plate serum subcutaneously.

Notes on blood picture and general condition.—July 1st: Pig lively. Well-marked firm infiltrate over abdomen and extending forward to thorax. Blood picture normal except for one or two red cells showing polychromatophilia. July 2nd: Hæmagglutination well marked. Some red-cell shadows. Irregularity in size of red cells commencing. Megalocytes of medium size showing polychromatophilia, but not numerous. Animal ill. Infiltrate softening; some skin hæmorrhages; gums of good colour. July 3rd: Hæmagglutination extreme. Blood very watery; oozing after vein puncture. Irregularity in size of red cells. Megalocytes showing polychromatophilia; a few deeply basophile red cells; some poikilocytes. A few normoblasts, some showing punctate basophilia of cytoplasm. Pig collapsed and cold. No eye changes visible. Post mortem: A few small punctiform hæmorrhages in skin. Glands do not show hæmolymp change. No eye changes. Bladder contained dark blood-stained urine. No hæmorrhages in internal organs.

" 2nd	5,504,000	328,000	84%	300 "

Death during night of July 2nd-3rd.

* At 5 P.M. received 1 c.c. anti-plate serum subcutaneously.

Notes on blood picture and general condition.—July 1st: Blood picture normal. Hæmagglutination well marked. Pig lively. Infiltrate not very well marked. July 2nd: Irregularity in size of red cells. Fair number of megalocytes, mostly showing polychromatophilia. Some red-cell shadows. Pig not well. Infiltrate more marked, but softer. Some skin hæmorrhages, one about the size of a threepenny-piece. Post mortem: Well-marked gelatinous blood-stained infiltrate. Numerous small punctiform hæmorrhages in skin. Glands of hæmolymp character. A few small hæmorrhages in lungs and in wall of left ventricle. Spleen much enlarged and friable. One or two minute petechiæ in pancreas. Bladder full of blood-stained urine. Numerous hæmorrhages in wall of large gut and in testicles.

Remarks on Tables II.A, II.B, and II.C.—These three animals, whose initial weights were 240 gm., 260 gm., and 360 gm., did not survive beyond the third day. All showed pronounced purpura. The effect of the serum on the blood elements is essentially similar to that obtained in the case of the larger animals of Table I. Notes regarding the minute changes in the red cells, the general condition of the animals during life, and the post-mortem appearances are appended to the tables.

Control Experiments with other Sera: Action of Anti-leucocytic Serum.

This serum was prepared by immunising rabbits with leucocytes obtained from the peritoneal exudates of guinea-pigs which were killed 4 hours after an intraperitoneal inoculation of 5-10 c.c. of sterile broth. Such exudates, as is

well known, consist almost entirely of polymorphonuclear leucocytes, and if great care is taken in manipulation of the animals after death the risk of admixture with red cells can be very largely avoided. The exudates are taken up in citrated saline and thereafter washed in normal saline. The serum of the rabbits so immunised proved to be quite as fatal to guinea-pigs as the anti-plate serum, but did not produce purpuric phenomena. We append two tables (Nos. III.A and III.B) showing the action of the serum on the blood elements throughout the course of the experimentally induced disease.

TABLE III.A.—Guinea-pig 15.

Date.	Red cells.	Plates.	Leucocytes.	Differential count.†				Hb.	Weight.
				P.	E.	L.	Ma.

" 11th	?	?	?	25.0%	2.0%	72.5%	1.5%	?	220

Death at 3 P.M. on July 11th.

* At 5.30 P.M. received 1 c.c. anti-leucocyte serum subcutaneously.

† P = Polymorphonuclears. E = Eosinophiles. L = Lymphocytes. Ma = Mast cells.

Blood picture and general condition.—July 9th: Red cells irregular in size; numerous polychromatophilic megalocytes; a few red cells showing "Jolly" bodies; no nucleated red cells. The polymorphonuclear leucocytes are degenerated, their protoplasm being vacuolated and the granules appearing as indistinct basophile knots in cytoplasm. Pig ill. Small infiltrate under skin; no skin hæmorrhages. July 10th: Large numbers of megalocytes; some microcytes; well-marked polychromatophilia; nucleated red cells (normoblasts) 1.5 per cent. of white cells. Some phagocytosis of red cells by mononuclears. General condition unchanged. No skin hæmorrhages. July 11th: Some red cells show punctate basophilia; nucleated red cells (normoblasts and megaloblasts) 21 per cent. of white cells. Neutrophile myelocytes present. Pig ill and collapsed; hæmoglobinuria; no eye changes. Post mortem: No skin hæmorrhages. Lymph glands appear normal. No hæmorrhages in internal organs. Spleen greatly enlarged and friable. Bladder full of blood-stained urine.

TABLE III.B.—Guinea-pig 16.

Pig dead at 6 P.M. on July 12th.

* At 5.30 P.M. received 1 c.c. anti-leucocyte serum subcutaneously.

Blood picture and general condition.—July 9th: Slight hæmagglutination. Irregularity in size of red cells; poikilocytes; polychromatophilic megalocytes; one nucleated red cell seen. Degeneration of polymorphonuclears as in No. 15. Pig seems ill. Very slight infiltrate; no skin hæmorrhages. July 10th: Marked irregularity in size of red cells; no nucleated red cells. Infiltrate soft; no skin hæmorrhages. July 11th: Many megalocytes showing polychromatophilia; some red cells with punctate basophilia; nucleated red cells (normoblasts) 3.5 per cent. of white cells. Phagocytosis of red cells observed. Myelocytes 4 per cent. (total neutrophiles, 34 per cent.). Pig very ill. No eye changes. Post mortem: No skin hæmorrhages. No eye changes. No hæmorrhages in internal organs. Spleen slightly enlarged. Hæmoglobinuria. Liver yellowish.

It will be seen from the tables that while the red cells were very considerably affected, the blood plates were not appreciably altered in number. The most striking phenomenon in connexion with this serum is the great but temporary fall in the absolute number of leucocytes. In this fall, as the differential counts show, the polymorphonuclear cells are chiefly involved. No hæmorrhages were seen on the skin during life or in the organs after death. In both cases hæmoglobinuria was a well-marked feature.

Action of Anti-red-cell Serum (Ordinary Lytic Serum).

The effects of injecting lytic serum into the animal whose red cells have been used for immunisation have been studied by several workers, and notably by Muir and McNee (1912),² who have experimented with anti-rabbit red-cell serum prepared by immunisation of the goat with rabbit red cells. No record has been found of the production of purpuric lesions by such sera. It was, however, considered advisable to prepare a lytic serum for comparative tests, and for this purpose rabbits were immunised with washed guinea-pig red cells in the usual way. This serum has been tested on guinea-pigs only in a few cases so far. It is very lethal for guinea-pigs, but no evidence has been obtained that it can give rise to generalised purpura. As we shall see later, an anti-rat-red-cell serum proved to be equally devoid of purpura-producing effects when injected into rats, whereas the anti-rat-plate serum consistently produced purpura.

The Question of Dosage of Anti-plate Serum.

To test this point four guinea-pigs, each exactly 250 gm. weight, received the following quantities of anti-plate serum subcutaneously in the dorsal region on June 2nd, 1914: 2 c.c., 1 c.c., 0.5 c.c., and 0.1 c.c. (volume in all cases made up to 2 c.c. with saline). The animal which received 2 c.c. died on June 6th, showing an enormous number of hæmorrhages, with petechiæ on the heart and lungs and double cataract. The animal which received 1 c.c. died on June 4th (i.e., after 42 hours). There was beautiful miliary purpura over the whole skin, with petechiæ on the heart and lungs. Cataract had not developed. The animal which received 0.5 c.c. developed, like the others, a local swelling which had practically disappeared on June 6th. It died ten days later, but showed no purpuric lesions either internally or externally. Very probably any such lesions that may have occurred and escaped detection in the early days after inoculation had faded. The animal which received 0.1 c.c. showed only very slight local swelling for a few days after inoculation, and remained well.

Experimental Purpura in the Rabbit.

An anti-rabbit-plate serum was prepared by immunising the goat with rabbit blood plates recovered from rabbit blood by a method similar to that employed in the case of guinea-pig blood. Each dose given to the goat consisted of the blood plates recovered from the mixed blood of 12 rabbits. About nine such injections were given. The serum of the goat was tested at various times during the course of immunisation, and it will be convenient to detail briefly the results obtained with this serum on various rabbits, as in certain cases highly interesting pathological lesions were

found at necropsy. In the earlier cases of the series purpuric lesions in the skin were unfortunately not searched for.

Rabbit 1.—Received on June 20th 4 c.c. anti-plate serum subcutaneously (from test bleeding of goat after three doses). June 21st: Considerable soft local swelling. June 23rd: Swelling very slight. Rabbit remained well till July 15th, when sudden death took place. Post mortem: Animal well nourished. Peritoneal cavity filled with clotted blood and extravasated faeces. *Two large fairly clean-cut perforations of the bowel just below cæcum. A few purpuric spots in small intestine. Some faded purpuric spot in skin, especially that of hind limbs. Large hæmorrhages in the psoas muscle and in the muscles over tibia and fibula. Effusions of blood in the periosteal sheaths of these bones. Stomach mucosa showed a cluster of minute hæmorrhages, but there was no general purpura of the organ. Liver and lungs healthy.*

Rabbit 2.—Received on June 20th 1.5 c.c. intravenously (test bleeding after four doses). Remained well.

Rabbit 3.—Received on June 30th 2 c.c. intravenously (test bleeding after four doses). Remained well till July 3rd, when it was given a further dose of 3 c.c. intravenously. Death occurred two hours thereafter. Post mortem: *Perforated ulcer of colon adherent by film of lymph to abdominal wall. Purpuric patches round the ulcer. The colon contained another large ragged ulcer with greyish scurf on it. It was not perforated. In the stomach were two similar large non-perforated ulcers. Right lung collapsed and congested. Some free blood in right pleural cavity. The liver contained a few nodules of pseudotuberculosis, so that some doubt remains whether the late purpuric lesions met with may have been of bacterial origin. This is, however, unlikely.*

Rabbit 4.—Small Russian. Received on July 6th 5 c.c. intraperitoneally (test bleeding after four doses). July 7th: Three or four purpuric spots in skin over sternum. July 8th: Very large number of purpuric spots on skin of abdomen and back, and especially of extremities. Petechiæ on ear. On the same day it received a further dose of 3 c.c. intraperitoneally. July 9th: Rabbit looks well. Received a third dose of 3 c.c. intravenously and died in convulsions five minutes afterwards. Post mortem: Enormous number of skin hæmorrhages. Miliary purpura of stomach. One or two petechiæ on epicardium, and a good number on large bowel and under kidney capsule. Very large number in skin covering fore and hind extremities and tail. No cataract. Large amount of free blood in peritoneal cavity. One or two reddish lymph glands in axilla and groin. Urine quite clear.

Rabbit 5.—Very small Russian weighing 440 gm. Received on August 27th 4 c.c. intraperitoneally (test bleeding after seven doses). August 28th: Animal looks fairly well. Numerous purpuric spots on skin of abdomen and extremities. Weight 431 gm. August 29th: Animal dead. Post mortem: Beautiful purpura of skin. *Extensive purpura of cæcum and large bowel. A few spots in small intestine and in stomach. Numerous petechiæ in diaphragm.*

Blood Changes in Experimental Purpura of the Rabbit.

We append three tables (Nos. IV. A, IV. B, and IV. C) in which are recorded the blood changes, &c., in the case of three rabbits inoculated intraperitoneally with the same dose (3 c.c.) of anti-rabbit-plate serum.

TABLE IV. A.—*Rabbit 33.*

Date.	Red cells.	Plates.	Leucocytes.	P.	E.	L.	Hb.	Coag. time.

* At 4 P.M. received 3 c.c. anti-rabbit-plate serum intraperitoneally.

† Killed with ether to obtain specimen of skin.

² Muir, R., and McNee: The Anæmia Produced by a Hæmolytic Serum, *Journal of Pathology and Bacteriology*, vol. xvi., p. 410.

Blood picture and general condition.—July 16th: Hæmagglutination present. Some irregularity in size of red cells; a few red cells showing polychromatophilia; one or two nucleated red cells seen. Rabbit quite lively. Bleeds very readily when ear vein is punctured; marked purpura over entire skin. July 17th: No nucleated red cells seen; a few showing polychromatophilia. Rabbit quite lively. No fresh outburst of purpura so far as can be detected. Post mortem: Extreme purpura of skin. Lymph glands not of frankly hæmolymp character. A few punctiform hæmorrhages in stomach and large gut. Some extensive hæmorrhages in muscles of thigh. No hæmoglobinuria.

TABLE IV.B.—Rabbit 34, weight 920 gm.

* At 4.15 P.M. received 3 c.c. anti-rabbit-plate serum intraperitoneally.

Blood picture and general condition.—July 20th: Before injection one or two nucleated red cells were seen in film. July 21st: Little change in red cells; one normoblast seen. Animal drowsy and unwell. Hæmorrhages in skin, and specially marked in skin of ears. The flicking or rubbing of the ears produces an immediate crop of small punctiform hæmorrhages. July 22nd: Many red cells showing polychromatophilia; marked irregularity in size of red cells; no nucleated red cells seen. Rabbit quite lively. Hæmorrhages still present in skin. July 23rd: Marked irregularity in size of red cells; some large megalocytes showing polychromatophilia; no nucleated red cells seen. Animal's condition good. July 29th: Animal's condition good. Purpuric spots in skin mostly faded. A few still present on ears.

TABLE IV.C.—Rabbit 35, weight 700 gm.

Killed with ether at 2 P.M. on July 23rd.

* At 4.45 P.M. received 3 c.c. anti-rabbit-plate serum intraperitoneally.

Blood picture and general condition.—July 20th: Before injection no nucleated red cells were seen. July 21st: Hæmagglutination present but not marked. Some irregularity in size of red cells; some poikilocytes; no nucleated red cells. Animal ill. Hæmorrhages in skin, and especially in skin of ears. July 22nd: No nucleated red cells. Animal's condition unchanged. July 23rd: No nucleated red cells. Condition unchanged. Post mortem: Skin shows numerous hæmorrhages. Lymph glands appear normal. Numerous intramuscular hæmorrhages in diaphragm. No hæmorrhages in stomach or intestine; no hæmoglobinuria. Some hæmorrhages of moderate size in thigh muscles.

It will be seen that all three animals developed marked generalised purpura from which they recovered. They were, however, killed for examination purposes at various dates, and the post-mortem appearances are appended to the tables. The marked and early fall in the plate content corresponding with the early onset of purpuric skin phenomena will be noted. In these rabbits coagulation times were taken by the Dale-Laidlaw method,³ the blood being drawn into short capillary

tubes, each containing a small shot. The data so obtained are included, but we are not satisfied that they can be depended upon, in view of the variations we have obtained by this method in normal rabbits examined at short intervals. This question is reserved for further investigation.

Experimental Purpura in the Rat.

Rabbits were immunised with rat platelets recovered from fairly large quantities of rat blood. Each immunising dose consisted of the plates obtained from the mixed blood of 24 sewer rats. Three rabbits were immunised, two of which died during the course of immunisation. From the remaining rabbit a small test bleeding was taken a few days after it received its second dose. The serum so obtained was tested on a rat and found to be efficacious in producing purpura (see below). The rabbit received a third and a fourth dose of rat plates, but unfortunately a few minutes after the intravenous injection of the latter dose it developed marked anaphylactic symptoms. It was felt that the serum of such an animal would probably be largely deprived of its anti-plate elements owing to absorption by the large dose of fresh plates injected. The animal was, however, bled when moribund and the serum so obtained filtered. As we shall see, this serum possessed marked purpura-producing property.

Effect of Injecting Anti-rat-plate Serum into Rats.

Rat 1.—Received on Sept. 29th 2.5 c.c. subcutaneously in dorsal region near root of tail (from test bleeding after second dose). Sept. 30th: Numerous minute skin hæmorrhages round the area of inoculation and along the tail. None elsewhere. Oct. 1st: The animal now moribund was killed with ether. Post mortem: A large oval skin hæmorrhage was found at site of inoculation, with smaller petechiæ at the periphery. Numerous hæmorrhages in skin of tail. A few in pyloric portion of stomach. No generalised skin purpura. The result, however, showed that the serum from this early test bleeding possessed the purpura-producing property.

Rat 2.—Received on Oct. 13th, 1914, 3 c.c. subcutaneously (from moribund rabbit after its fourth dose). Oct. 14th: A few petechiæ noted on skin of hind limbs. Oct. 15th: Animal not examined. Oct. 16th: Animal very ill and drowsy; was accordingly killed with ether. Post mortem: Beautiful generalised skin purpura. Large hæmorrhage in muscles of one fore limb; marked purpura of tail. Several small hæmorrhages in pyloric portion of stomach. Lymph glands bright red in colour. No hæmoglobinuria. No cataract.

Rat 3.—Received on Oct. 14th 4 c.c. subcutaneously. Oct. 15th: Cluster of small hæmorrhages near site of inoculation. Oct. 16th: More hæmorrhages in the neighbourhood. Animal very ill and drowsy. Oct. 17th: Rat dead. Post mortem: Generalised skin purpura. Red lymph glands throughout. Petechiæ in pyloric portion of stomach and throughout a considerable part of the small intestine, also in sigmoid and rectum. Urine in bladder blood-stained.

On the whole, the lesions in rat purpura are essentially similar to those met with in experimental guinea-pig purpura except that cataract, so frequently found in guinea-pigs dying of the experimental disease, has not so far been noted in rats. As mentioned above, the effect of anti-rat red-cell serum was investigated on rats. No purpuric lesions resulted.

Action of Heterologous Anti-plate Sera.

The question of the specificity of these anti-plate sera is of importance, and at various times control experiments in settlement of this point have been made. Invariably the result has been that the animal does not respond to the heterologous anti-plate serum—e.g., only slight inconvenience and certainly no purpura follow the

³ Dale, H. H., and Laidlaw, P. P.: A Simple Coagulometer, Journal of Pathology and Bacteriology, vol. xvi., p. 351.

injection of the guinea-pig with anti-rabbit-plate serum, and *vice versa*. Recently, being in possession of a supply of anti-guinea-pig-plate, anti-rabbit-plate, and anti-rat-plate sera, one of us has carried out the following experiment, which shows clearly that a heterologous anti-plate serum has no purpura-producing property.

TABLE V.

Rat A, 150 gm.,	received 7/12/1914,	3 c.c. anti-rat-plate serum.
" B, 90 "	" "	3 " anti-guinea-pig-plate serum.
" C, 140 "	" "	4 " anti-rabbit-plate serum.
(All inoculated subcutaneously.)		
Guinea-pig A, 230 gm.,	received 7/12/1914,	3 c.c. anti-guinea-pig-plate serum.
" B, 230 "	" "	3 " anti-rat-plate serum.
" C, 230 "	" "	4 " anti-rabbit-plate serum.
(All inoculated subcutaneously.)		
Rabbit A, 400 gm.,	received 7/12/1914,	4 c.c. anti-rabbit-plate serum.
" B, 380 "	" "	4 " anti-guinea-pig-plate serum.
" C, 380 "	" "	4 " anti-rat-plate serum.
(All inoculated intraperitoneally.)		

On Dec. 8th Rat A showed several purpuric spots near tail and also on legs. Other two rats showed nothing and appeared quite lively. Guinea-pig A had an extensive hæmorrhagic infiltrate over the whole of the abdomen and did not appear well. The other two animals showed no purpura and were quite lively. Rabbit A had numerous purpuric spots all over its skin and was obviously ill. The other rabbits were quite lively and showed no purpura. On Dec. 9th the animals inoculated with the homologous sera were still more drowsy and listless. Other animals appeared quite well. On Dec. 10th Guinea-pig A and Rabbit A dead.

Post mortem: Guinea-pig A showed beautiful skin purpura, extensive cedematous and hæmorrhagic infiltrate spreading over abdomen from seat of injection and extending deeply into the thigh muscles, and miliary purpura of stomach. There was no cataract, and the urine was quite clear. Rabbit A showed a large cedematous and hæmorrhagic subcutaneous area over upper thorax, neck, and fore limbs, also a larger hæmorrhage under skin of left cheek. Miliary purpura of stomach and slight purpura of intestine. Liver yellow and mottled. No cataract. Urine quite clear.

The other animals remained well and put on weight.

Dec. 11th: Rat A dead. Post mortem: Purpura of skin particularly marked over skull and cheek. A few spots in pyloric portion of stomach and a few in small intestine. Urine was blood-stained (hæmoglobinuria).

The other animals, which received the heterologous plate sera, remained well and put on weight.

Summary and Conclusions.

1. Data have been recorded on the blood changes in guinea-pigs after inoculation with anti-guinea-pig-plate serum. The early fall in the number of platelets simultaneously with the outburst of skin purpura is found to be a marked feature.

2. Purpura has also been produced in rabbits and rats by inoculation with the respective anti-plate serum. The blood changes in rabbits have been followed with results similar to those obtained in guinea-pigs.

3. Anti-plate serum, in addition to its purpura-producing properties, possesses in common with other cytolytic sera considerable lytic powers, which in all probability contribute largely towards the fatal issue in small animals. Death, however, may occur as the result of extensive hæmorrhages alone without any obvious lytic changes as evidenced by hæmoglobinuria.

4. Sera obtained by immunisation with red cells or leucocytes do not produce purpura.

5. Purpura is not produced by inoculating animals with heterologous anti-plate sera.

The histology of the purpuric lesions will form the subject of a later communication.

A CONTRIBUTION TO THE STUDY OF SHELL SHOCK.

BEING AN ACCOUNT OF THREE CASES OF LOSS OF MEMORY, VISION, SMELL, AND TASTE, ADMITTED INTO THE DUCHESS OF WESTMINSTER'S WAR HOSPITAL, LE TONQUET.

By CHARLES S. MYERS, M.D., Sc.D. CAMB.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

THE remarkably close similarity of the three cases which are described in this paper is shown in the following synopsis:—

	Case 1.	Case 2.	Case 3.
Cause...	Shells bursting about him when hooked by barbed wire.	Shell blowing trench in.	Shell blew him off a wall.
	Preceding period of sleeplessness.	As in Case 1.	?
Vision ...	Amblyopia. Reduced visual fields.	"	As in Case 1.
Hearing ...	Slightly affected for a brief time.	Not affected.	As in Case 2.
Smell ...	Reduced acuity.	Total anosmia.	Unilateral anosmia and parosmia.
Taste ...	Almost absent.	Reduced acuity.	As in Case 2.
Other sensations ...	Not affected.	As in Case 1.	As in Case 1.
Volitional movements	"	"	"
Defecation	Bowels not opened for five days following shock.	"	"
Micturition	Urine not passed for 48 hours.	Not affected.	As in Case 2.
Memory ...	Apparently slightly affected.	Very distinct amnesia.	"
Result of treatment	Gradual improvement by rest and suggestion.	As in Case 1, supplemented by hypnosis	As in Case 1.

CASE 1.—Private, aged 20. Admitted on Nov. 5th, 1914. On the nights of Oct. 28th and 29th he slept in the booking hall of X station; "not much sleep there." On the 30th he motored in a bus from X to Y, arriving there at 7.30 P.M.; billets found at 8 P.M.; on guard from 10–11.30 P.M., and from 1.45–3.45 A.M. At 11 A.M. on the 31st for the first time he went to the firing line. His platoon advanced to one set of trenches and then crossed the road to another, only to find it filled with cavalry and to be told that there was no room for them. During the retirement from this trench, at 1.30 P.M., they were "found" by the German artillery. Up to that time he had not been feeling afraid; he had "rather been enjoying it," and was in the best of spirits until the shells burst about him.

He was now retiring over open ground, kneeling on both knees and trying to creep under wire entanglements, when two or three shells burst near him. As he was struggling to disentangle himself from the wire three more shells burst behind and one in front of him. (An eye-witness in this hospital says that his escape was a sheer miracle.) After the shells had burst he succeeded in getting back under the wire entanglements; all his comrades had retired already. He managed to get into a trench, and as the firing slackened he rejoined his company. Immediately after the shell had burst in front of him his sight became blurred. It hurt him to open his eyes, and they "burned" when closed. The right eye seemed to have "caught it" more than the left. At the same moment he was seized with shivering, and cold sweat broke out especially round the loins. He thinks the shell behind him gave him the greater shock—"like a punch on the head, without any pain after it." The shell in front out his haversack clean away and bruised his side, and apparently it burned his little finger. It was this shell, he says, which "caused his blindness."

Falling in with two comrades, he was led by them, one on either side, to the dressing station. He opened his eyes occasionally to see where he was going, but everything

appeared blurred except at the first moment of opening. There was no doubling of objects; they seemed to "dissolve." He was crying the whole time and worrying as to whether he was going blind. He kept turning over in his mind the succession of events from the beginning of the advance to the bursting of the shells. At the dressing station he was still crying and shivering; he was taken thence to a hospital by horse ambulance, where he was given brandy, and then sent on by horse ambulance to another hospital, and thence by motor ambulance at night to X, where he arrived early on Nov. 1st. He thinks he must have slept on the ambulances, as he remembers nothing.

From Nov. 1st to 4th at X; his eyes were bandaged and drops were instilled which "burnt terribly." No numbness or anaesthesia observed. Slight deafness, which soon passed off. On Nov. 1st he shivered in bed almost incessantly; his thoughts were still running on events between the advance and the bursting of the shells. No shivering after Nov. 3rd. He says he did not micturate from Oct. 30th P.M. until Nov. 2nd P.M., and did not defecate from Oct. 30th until Nov. 5th (after aperient here). No involuntary passage of urine or feces.

Past history.—He had been for two months in the Aisne district on the lines of communication, sleeping badly all that time owing to lumbar pains (and toothache during the first three weeks). He had failed to pass a medical examination some time previously because of renal trouble (abnormal amount of albumin in water) until after a long period of treatment. He had had lumbar pains a few nights before coming to France.

Present condition.—Nov. 6th.—A well-nourished man of nervous temperament, flushed complexion, and dark eyes. Movements normal; skin sensations normal. Eyes, fundi normal. Fields distinctly contracted, especially on temporal sides. Right eye—can read at normal distance, but "things have a slight haze round them." Left eye—the haze is much greater; is unable to see letters until they are quite near.

Nov. 7th.—Says he has lost his sense of taste and smell since the shells burst round him. Gets up now.

Nov. 9th.—Woke up last night and found himself crying, "not thinking of anything in particular"; he at once "pulled himself together."

Nov. 10th.—Tested for taste (tongue protruded) and smell in order mentioned:—

- (1) Very strong sol. of sugar ... Slightly sweet (only tasted after the tongue had been moved about).
- (3) " " " salt ... No taste.
- (4) " " " acid ... No taste, but "a peculiar feeling as if it dried the tongue."
- (7) " " " quinine... No taste (later, "a peculiar feeling of biting on the tongue").
- (5) Carbolic acid (1:40) ... No smell.
- (6) Ether ... Faint smell, like collodion.
- (8) Peppermint (strong) ... Faint smell of peppermint.
- (2) Tincture of iodine ... No smell.

Hypnosis tried; patient explains later—"I insisted on resisting." Suggestions offered during concentration. Nov. 15th.—Says his taste and smell are returning. Fields of vision still restricted, perhaps slightly less so. Nov. 15th.—He was transferred to England for further treatment.

On Nov. 16th the patient was admitted to the Middlesex Hospital, London, under the care of Mr. Arnold Lawson, who has kindly allowed me to append his note of the condition of the patient's eyes:—

Nov. 25th: R. E.	+1.75	L. E.	-1
	+2.25		+2

Visual acuity, each eye 6/36; when under correction 6/18. Just below and to the outer of the left disc is a small clear buff patch in the choroid. The upper inner margins of the discs are somewhat blurred and more densely white than elsewhere. These features are probably not pathological. The fields are definitely restricted, especially on the nasal side of the retina, being limited here to 40° in the right eye and to 70° in the left. No central scotoma. Taste and smell were found affected on admission, but these recovered earlier.

Nov. 27th.—General condition improved. Not so "nervy." Visual acuity under correction, R.E. 6/24, L.E. 6/18. The patient is now (Feb. 1st) attending the hospital as an out-patient.

CASE 2.—Corporal, aged 25. Admitted on Dec. 11th, 1914. The patient says that he was buried for 18 hours on Dec. 8th owing to a shell bursting and "blowing in" the trench in which he lay. Can remember nothing until he found himself in a dressing station at a barn lying on straw. He says that then he could not see and that for this reason he fell over something when he got up and walked about there. As to his past history, he came out to the war on August 13th, and was in the last two days' retreat at Mons and after at La Bassée. Has slept very badly since the start, often when billeted taking large doses of whisky to procure sleep. Has led a "fast" life and has had recent domestic worry.

Present condition.—Dec. 12th.—A healthy-looking man with flushed face and large dark eyes with wide pupils. His general manner does not inspire one with confidence in his reliability. Complaints of pains in chest, then, back and limbs, and of difficulty in seeing. The pains are chiefly in the knees and ankles. His sight has been very indistinct since he was "buried." Says that if he looks at an electric light it takes him "five minutes" before he can see anything again. His vision has much improved since Dec. 8th, but he can only read when the type is close to his eyes and not for long; "it all becomes blurred." Heart, lungs, and joints appear normal. Abdomen distended and tender in lower part. Bowels not opened for five days. Aperient is effective. Vision: R.E. 5/60, L.E. 2/60. Media clear. Fundi natural.¹ Pupils and eye movements normal. Hearing normal.

Dec. 17th.—Smell: Fails to smell peppermint, ether, iodine tincture, and carbolic acid (1:40). Taste (tongue protruded): Very strong solution of sugar—tasted only after movements of tongue are allowed. Very strong solution of salt—"feels like petrol does on the hand," tasted only after movements of the tongue are allowed. Solution of acid—"salty, like alum."

Dec. 19th.—Complains that he does not sleep, but the sister in charge of his ward says that he sleeps well. Treatment by suggestion (during and without hypnosis) was begun, and continued daily until patient's transfer to England. On the second trial and afterwards a state of light hypnosis was easily induced. The deeper stages, involving hallucinations, anaesthesia, and post-hypnotic amnesia, could not be reached on any occasion. But the lighter stages (in which the patient responded to suggestions that he could not open his eyes, close his hand, stop laughing, and the like) sufficed to bring about assurance of a good night's sleep, gradual restoration of memory, and (later) improvement in visual and olfactory acuity, in near vision, in visual fields, and in colour sensibility. The improvement in visual acuity and near vision is shown in the following table:—

	Visual acuity. Both eyes.	Near vision.	
		Right eye.	Left eye.
Dec. 15th.	Before hypnosis, 5/60.	No. 15 Jaeger (badly).	Less than No. 15 Jaeger.
" 23rd.	After " 3/36.	No. 12 Jaeger	No. 15 Jaeger (badly).
" 26th.	Before " 1/6.	No. 6 "	No. 12 Jaeger
" 27th.	After " —	No. 4 "	No. 10 "
" 27th.	" 2/6.	No. 2 "	No. 10 "
" 28th.	No " 4/6.	No. 1 "	No. 4 "

¹ Colonel W. T. Lister, A.M.S., reports (Dec. 15th) that under homatropine and cocaine the refraction of the patient's eyes is as follows:

R.E.	+2.5	L.E.	-1?
	+2.5		0 or -0.5

He makes at the same time the following note on the fundi: "Right eye: Sector below disc is deficient in retinal pigment, so that the choroidal vessels are abnormally visible, but there is no pathological pigmentation and there are no areas of atrophy. Left eye: Internal crescent; vessels drawn to nasal side; and lack of retinal pigment on nasal side (nasal staphyloma). The atrophic appearance is more marked in this eye; even the choroidal pigment is deficient, giving a pale area. Maculae normal. Both discs pale, and there is connective tissue by the sides of the vessels. The whole condition, in my opinion, might be congenital."

The improvement in visual fields is shown on the annexed Chart 1.² The "functional" character of this restriction of fields is shown by the fact that the patient was never observed to collide with objects when walking, and that he was able to box here when convalescent.

The improvement in colour sensibility was as follows:—
Dec. 14th: Half-inch square of colour recognised at 22 cm. R.E., 7.5 cm. L.E. Dec. 27th: 350 cm. R.E., 50 cm. L.E.
The sensibility of the eyes to red appeared to be keener than

a bit' when they got me out. I got up and then fell down, and it was all a 'wash out.'

Under hypnosis he confirms the above, adding that in his struggles in the trench he "said a prayer or two," and that when he fell asleep he thought himself in the R. Hotel at S., where he had lived for years and is well known. "I was listening to a young lady I know [not intimately] playing the piano. I saw Mr. S. [the landlord] and Mrs. S. The sleep and dreams kept coming and going. It was

CHART 1.

Perimeter charts from Case 2. A, Dec. 14th; A₁ at start, A₂ after testing other eye; B, Dec. 21st; C, Dec. 26th, C₁ before hypnosis, C₂ after hypnotic suggestion; D, Dec. 27th; E, Dec. 28th.

that to any other colour. Thus the red square was recognised at 100 cm. by the left eye on Dec. 27th, while other colours (yellow, blue, and green) could only be recognised at 50 cm. So, too, on Dec. 14th the visual field for the recognition of coloured squares was limited in both eyes to the fovea save in the case of red, the field for which in the right eye extended definitely, though slightly, beyond the fovea towards the nasal side of the retina.

The improvement in olfactory acuity is shown by the fact that on Dec. 27th he was able to smell and to recognise ether, peppermint, camphor, and turpentine, although still unable to smell carbolic acid (1:10), tincture of iodine, or methylated spirit.

The gradual restoration of memory occurred as follows:—
Dec. 22nd.—During hypnosis suggestions made evoked a description of how the ground fell in on him at the trenches. He says that he was buried up to the neck and that Sergeant L. dug him out. Men of the N. Regiment (not of his own regiment) took him to their dressing station, but the medical officer there "packed him off" to the dressing station of the M. (his own) Regiment. He can now remember Captain S. (attached to his regiment from the —) speaking to him and giving him a drink. He spoke to him when he reached the barn (the M.'s dressing station). While under hypnosis the patient is told that he will remember this when he awakes. He does so, but cannot explain why he had not been able to recall it before.

Dec. 23rd.—To-day, before hypnosis, he remembers another "big hospital" to which he was taken on leaving the barn—a "big square room with a stove in the centre"—opposite which he was placed. But he cannot recall how he got there, or how he left to come here by train. He cannot remember being carried on a stretcher until they took him out of the train at Etaples (the railway station for this hospital). He says that there was "no light" in the barn all the time he was there (24 hours). He remembers struggling in the trench "for hours" after he was buried. Finally he gave it up. "I went to sleep, and was enjoying myself at home when they started 'messing me about.' Someone fell on me and woke me up. I 'tumbled to things

dark when they dug me out. After I got out a chap said 'the fellow's mad,' and I said 'You're a liar.' Now, I remember a place between the barn and the hospital, rather a smart building, a long, low place. I was on a stretcher there. I must have got there by a horse ambulance, but I cannot remember this."

Dec. 26th.—Before hypnosis he recalls going to the clearing hospital (just mentioned) from the barn in a horse ambulance on a stretcher at midnight. He says: "I can remember talking to a major the next morning and having a sleeping draught at night. Then I went to another hospital at B. I had a ride in a motor ambulance on a stretcher, but whether this was from or to that hospital I cannot remember. I remember the journey in the train here distinctly. There were continual offers of tea, cocoa, sweets, and cigarettes. They wouldn't let us sleep for these things. I had a bad headache all the way down from the trenches. I did not bother much about my sight, as I thought it was imaginary. It wasn't until I got rid of the pain in my stomach which I came in with that I began to find my sight wouldn't let me read."

Dec. 27th.—While in hypnosis he gives the name of the man in the same trench with him as K. He "sees" very clearly the position of the trenches, their shallowness and covering. He remembers that he had been two days in the reserve trenches before he was sent on Dec. 7th to the firing line. He says, "The explosion lifted us up and dropped us again. It seemed as if the ground underneath had been taken away. I was lying on my side, resting on my hand, when the shell came. I got my right hand loose, but my left was fixed behind a piece of fallen timber. At last I dropped off to sleep and had funny dreams of things at home. One dream in particular I have thought over many times since. I haven't been able to make out why I should dream of the young lady playing the piano. I don't know her name and don't think I have seen her above twice."

Dec. 29th.—Before hypnosis he says that he can now "see" the N.'s dressing station—a one-storeyed house with two non-communicating rooms. He was taken first into the left-hand room, and later into the other in which the medical officer sat. No further information obtainable under hypnosis. He cannot recall how he got to the N. dressing station from the trenches.

² My thanks are due to Colonel Lister, A.M.S., who, by presenting the hospital with a portable perimeter and test types, made these observations now possible.

To recover the memory of this period other methods, in addition to hypnosis, were vainly tried. His dreams were generally of incidents belonging to earlier periods of the war, never of the trench-shelling. Attempts to obtain revival of the lost memories by getting him (a) to concentrate his attention on the scene of the shell bursting or of the N. dressing station, or (b) to record his thoughts when in a state of reverie, were fruitless.

How far the patient's memory, so far as it returned, can be trusted is not altogether certain. A man of the same regiment happened to be warded here at the time. He believes that the patient could not have remained in the trench for longer than an hour after the shell had burst. He declares that he saw him get out of the trench and report himself sick to Corporal R., and that he heard Corporal R. tell the patient to go off on foot to the M. dressing station. Until the day after the patient's arrival at the barn he never saw the patient again, when he was brought in himself there. He says that the doctors at the barn considered the patient "off his head." He does not believe that the N. Regiment was anywhere in the neighbourhood. He says that the man K. had been mortally hit some days before.

On further examination the patient says he has no recollection of reporting himself to Corporal R. or of meeting his fellow patient while at the barn, and he is quite certain that *somehow* he reached the N.'s dressing station before he got to his own.

On the other hand, another fellow patient here happened to belong to the N. Regiment and was able to confirm the patient's account by stating that the trenches of the N. Regiment were on that day

and was then brought, as he avers, to the dressing station by men of the N. Regiment. But of this last point the patient is not now so certain. He still insists that a man stepped into his fallen trench on top of him.

On Dec. 30th the patient was transferred to England for further treatment, and on the 31st he was admitted to the London Temperance Hospital under the care of Mr. J. S. Hosford, whence he has, I understand, now been discharged.

CASE 3.—Private, aged 23. Admitted on Jan. 26th, 1915. The patient says that he was blown off a heap of bricks 15 feet high owing to a shell bursting close to him. Thinks he must have fallen into a pool of water, as he next remembers finding himself, about 3 P.M. the same afternoon, in a cellar near a church with his clothes drenched. He does not know how he got there or how he left the cellar, but he remembers being in another hospital before he was admitted here. He cannot say if anyone was in the cellar with him. He remembers someone in the train talking to him and reminding him of being in the cellar.

Present condition.—Jan. 27th.—A healthy-looking man, well-nourished, but obviously in an extremely nervous condition. He complains that the slightest noise makes him start. His legs feel weak, and he has pain in the precordial region. His *sight has been very much impaired* since the shock. Distant vision, he says, is affected, and objects and type become blurred when long looked at. He has slept very little the last two nights. Heart, lungs, and joints appear normal. Abdomen, general spasm of muscles of wall on being touched. Hands tremulous. Knee-jerks normal, but the first attempts to evoke them provoked a spasm of the calf muscles and a few general convulsive movements as the patient lay in bed. His hands became very tremulous and his forehead sweated profusely. He appeared as if about to faint, and says that he felt cold and dizzy, and experienced "round and round movements of the stomach." The slightest touch on the

CHART 2.

Perimeter charts from Case 3, showing contraction of fields.

immediately next to those of the M. Regiment, and that the N. and M. dressing stations were situated in the same village, the former in a cottage about three-quarters of a mile beyond the latter, so that one would have to pass the M. dressing station on the way from the trenches to the N. dressing station.

There is hence a possibility that the patient wandered in a state of somnambulism from the trench past his own dressing station to that of the N.'s or that he wandered first into the N. trenches

legs provoked well-marked spasm of the quadriceps muscles of the same thigh. Plantar reflexes not obtainable. Extensor muscles of the toes appeared to be in a state of tonic contraction.

Jan. 30th.—Slept well last night for the first time. Bowels not opened for five days since the shock. Took an aperient last night and this morning; bowels open to-day. Eyes: Fundi normal. Fields, distinctly contracted, as in Chart 2. Near vision, either eye, No. 14 Jaeger; less for short words. Visual acuity (investigated by Colonel Lister, A.M.S.)—at first 6/24, but improved by encouragement and the indiscriminate use of weak + or - lenses to nearly 6/6.

Smell: Has complained until to-day of a *subjective sensation* of the odour of cordite. This has left him "since the bowels were open." *Left nostril fails to detect* smell of ether, peppermint, eucalyptus, ammonia, carbolic acid, or iodine tincture, all of which, save the last, are at once recognised when placed beneath the right nostril. No signs of nasal obstruction. *Taste*: Only tastes very strong solutions of sugar, salt, and acid, and then only when the tongue has been withdrawn and moved about the mouth; the taste is described as "faint."

Feb. 1st.—He complains that he gets very excited when anyone addresses him. He still fails to remember how he got to the cellar, but he now remembers someone there asking him his name and regiment. He says: "When I got into the hospital before I came to this one I can now remember being put against a wall and then being taken into a small room to see the doctor, who gave me a ticket and told me I was suffering from concussion. I think I must have gone to sleep after this, as I don't remember anything else until I was in the train. There a Royal Army Medical Corps bearer brought me a German prisoner to talk to. He was in the Bavarian Guard and had just seen his first action."

[Patient is still under treatment.]

Comment on these cases seems superfluous. They appear to constitute a definite class among others arising from the effects of shell-shock. The shells in question appear to have burst with considerable noise, scattering much dust, but this was not attended by the production of odour. It is therefore difficult to understand why hearing should be (practically) unaffected, and the dissociated "complex" be confined to the senses of sight, smell, and taste (and to memory). The close relation of these cases to those of "hysteria" appears fairly certain.

I have to thank Captain W. P. S. Branson and Captain H. Pritchard, R.A.M.C., in whose wards these patients were placed, for permission to make these investigations, and Major Gordon Watson, R.A.M.C., Commandant, for permission to publish them.

THE PSEUDO-LÆVULOSE OF DIABETIC AND OTHER URINES.

By P. J. CAMMIDGE, M.D. LOND.,

AND

H. A. H. HOWARD, B.Sc.

In a previous paper¹ we pointed out that the lævulose usually met with in urine, unlike the lævorotatory sugar of plant origin, is precipitated from acid solutions by basic lead acetate, resembling in this respect glucuronic acid. This observation appears to have been first made by Külz, who published in 1890 a paper² giving the result of his analyses of the so-called urinary lævulose. Like plant lævulose, this substance reduces copper and bismuth in alkaline solutions, is lævorotatory, and is fermented with brewer's yeast. Külz also found that with phenylhydrazine it gave an osazone which in appearance, melting point (205° C.), and on analysis corresponded to dextrosazone. According to his analysis it has a formula $n\text{CH}_2\text{O}$. Unlike plant lævulose, however, it could not be obtained in a crystalline form, but was only secured as a syrup. The rate at which it reduced copper solutions, its rapidity of fermentation, and its specific rotatory power, but above all the ease with which it was precipitated by hydrates of the heavy metals, further suggested that urinary

and plant lævulose were not identical substances. Other workers have since published similar results, but no attempt appears to have been made to establish the exact nature of the substance.

In diagnosing lævulosuria reliance has been placed upon a generally positive reaction with Seliwanow's test and the different readings obtained by reduction and the polarimeter. Borchardt, using a modification of Seliwanow's test, has claimed that lævulose does not occur in the urine, and that previous statements to the contrary were due to want of care in testing for it. In his modification the urine is treated with hydrochloric acid and resorcin, made alkaline with sodium carbonate, and then extracted with ethyl acetate. On carrying out this test with a solution of plant lævulose the ethyl acetate extract is coloured red, but with urines giving the ordinary Seliwanow reaction the watery solution retains the pigment and the extract is yellow.

These results obtained with Borchardt's test would be explained if, instead of lævulose, an acid with the constitution, $\text{CH}_2\text{OH}(\text{CH.OH})_3\text{CO.COOH}$ were present. The reaction would then be—

—and this derivative being a ketonic acid would dissolve in the sodium carbonate solution and not be extracted by the subsequent treatment with ethyl acetate. If, however, lævulose were present the following reactions would occur:—

—and the furfuryl derivative being non-acid in character would not be soluble in the sodium carbonate solution, and hence would be extracted by the ethyl acetate. Since the unmodified Seliwanow and Pinow reactions are readily obtained in a considerable number of cases, and in view of Borchardt's claim that true lævulose never occurs in the urine when tested for by his method, it seemed to us that the so-called lævulose might be the hitherto undescribed ketonic acid, of which we have just given the formula. This formula would explain its resemblance to glucuronic acid with respect to lead acetate, and would also admit of the formation of an insoluble calcium salt and a characteristic methylphenylhydrazine derivative.

In order to investigate these points and to establish the identity of the substance specimens were prepared by the following procedure:—

The urine was concentrated to a fifth of its volume and a saturated solution of lead acetate added, using one-tenth of the original volume of urine taken. The mixture was then heated on a water bath at 90° C., cooled, filtered, and the precipitate washed with water. The precipitate was suspended in 100 c.c. of a saturated solution of sodium sulphate and digested for two hours, when it was diluted to 500 c.c., filtered, and the filtrate tested for lead. When all the lead was found to have been removed the filtrate was mixed with 50 c.c. of saturated calcium chloride solution and 50 c.c. of lime water. After standing for two hours the precipitate that had formed was filtered off, well washed

¹ THE LANCET, Sept. 26th, 1914, p. 791.

² Zeitschrift für Biologie, Band xxvii., p. 228, 1890.

with water, alcohol, and ether, and dried. The calcium content of the salt prepared in this way was determined in 6 cases with the following results: (i.) 9.4 per cent., (ii.) 9.5 per cent., (iii.) 9.2 per cent., (iv.) 9.3 per cent., (v.) 9.4 per cent., and (vi.) 9.6 per cent., an average of 9.4 per cent., which corresponds closely to the theoretical calcium content, 9.39 per cent., of a salt with the formula $(C_6H_7O_7)_2Ca$.

To separate the free acid from the calcium salt it was suspended in water and a stream of carbon dioxide gas passed through for two hours. The calcium carbonate precipitate was then filtered off, and the filtrate concentrated by evaporation *in vacuo* over sulphuric acid. A thick, yellowish, hygroscopic syrup, from which no crystals separated, even after several months, was obtained. It had a sweetish acid taste, was levorotatory, fermented with brewer's yeast, rapidly reduced alkaline solutions of copper and bismuth, and gave both Seliwanow's and Pinow's tests.

The phenylosazone and parabromphenylosazone were then prepared by the method of Maquenne, and the melting point determined on the "bloc Maquenne." The phenylosazone separated out as rather coarse yellow crystals arranged in sheaves. The purified product in all the cases examined had a melting point of 223° C., which is 7° lower than the melting point of dextrosazone and lævulosazone. The percentage of nitrogen in the osazone was determined in two cases by Dumas's method, giving in one instance 14.80 per cent. and in the other 14.99 per cent. These results suggest that the formula of the compound is probably—

—with a theoretical yield of 14.97 per cent. of nitrogen.

The parabromphenylosazone was obtained as fine yellow felted needle-like crystals. In 4 cases of simple "lævulosuria" it was found to have the following melting points: (i.) 196° C., (ii.) 197°, (iii.) 197°, and (iv.) 198°. While in 5 cases in which the substance had been isolated from the urine of diabetics in which dextrose was also present the following results were obtained: (i.) 198° C., (ii.) 197°, (iii.) 198°, (iv.) 198°, and (v.) 196°. The close correspondence of the melting points in diabetic and non-diabetic cases suggests that the levorotatory substance is the same in both. The percentage of nitrogen present in the parabromphenylosazone was determined in two of the cases, one yielding 10.56 per cent. and the other 10.40 per cent., results which correspond to the theoretical yield of 10.52 per cent. for an osazone with the formula—

It will thus be seen that the melting point and nitrogen content of the phenylosazone and parabromphenylosazone do not correspond to the osazones formed by true lævulose, but that they point to the levorotatory substance which occurs in the urine, both in diabetic and non-diabetic cases, being a ketonic acid. To confirm this a study of its oxidation products was undertaken.

10 c.c. of the syrup prepared in the manner previously described were dissolved in 100 c.c. of water and heated with 20 gm. of lead peroxide and 10 gm. of sulphuric acid on a water bath for three hours. The mixture was then cooled and filtered. The filtrate was treated with barium carbonate until the acid was neutralised, then boiled and filtered. The filtrate was shaken with animal charcoal, filtered, concentrated to 50 c.c., and mixed with 100 c.c. of absolute alcohol. After standing for four hours the mixture was filtered. The precipitate was then washed with absolute alcohol, dried, and the barium content determined. 0.7428 gm. was found to give 0.3718 gm. of barium sulphate, corresponding to 29.46 per cent. of barium for the original compound. This yield corresponds, within the limit of experimental error, to the theoretical yield of 29.40 per cent. of barium for barium arabonate, $Ba(C_6H_7O_7)_2$, the

oxidation product produced by the action of lead peroxide on an acid of the formula, $CH_2.OH.(CH.OH)_3.CO.CO_2H$.

To confirm the presence of arabonic acid a portion of the salt was dissolved in water and the barium precipitated by carbon dioxide gas, the excess of which was subsequently removed by boiling. After filtering off the precipitate of barium carbonate, the solution was evaporated *in vacuo* over sulphuric acid. In five days white crystals appeared, and these were found to have a melting point of 97° C. corresponding to that of arabonolactone. These results pointed to a structural formula of—

This substance, from its analogy to glucuronic acid, we propose to name isoglucuronic acid.

In the course of our investigations we have examined specimens of urine from 30 cases of so-called lævulosuria and 50 of diabetes, in which a levorotatory substance was present along with the dextrose, but in none of them could any true lævulose be found, the levorotatory body in each instance being proved to be isoglucuronic acid. The data upon which a diagnosis of lævulosuria has been based in most of the published cases are such that the results obtained might equally well be explained by the presence of isoglucuronic acid, for the reduction of Fehling's solution, a positive Seliwanow's reaction, levorotation, these properties being abolished by previous fermentation with yeast, and the formation with phenylhydrazine of an osazone which has the melting point of glucosazone are characters shared by both bodies.

In some of the more recent cases reliance has been placed upon the formation of a crystalline calcium compound and the separation of a methylphenylhydrazine derivative with a melting point of 153° C.; but, as we have shown, isoglucuronic acid forms an insoluble compound with calcium, and we have found that with methylphenylhydrazine it yields an osazone which melts at 150° C. The difference between the two melting points is so slight that it cannot be relied upon as a means of differentiating the substances, especially as we have found that the melting point of methylphenyllævulosazone is not very sharp and is consequently difficult to determine with certainty. That this is the case is also suggested by the fact that melting points of 153° C.,³ 159° C.,⁴ and 158°–160° C.⁵ for the compound are given in recognised text-books. In support of our contention that isoglucuronic acid and lævulose are distinct substances, it may be mentioned further that a mixture of equal parts of the methylphenylosazones prepared under identical conditions has been found to melt at 120–130° C. on the "bloc Maquenne," whereas the osazone of lævulose melts at 162° C. and that of isoglucuronic acid at 155° C. The only published case in which it seems to have been conclusively proved that lævulose was present in the urine is that described by Otto Neubauer,⁶ for in this instance the sugar was isolated in a crystalline

⁶ *Münchener Medizinische Wochenschrift*, 1905, Band li., 1525.

form, which is impossible with isoglucuronic acid. Moreover, the crystals were found to be soluble in absolute alcohol, but were insoluble in a saturated alcoholic solution of lævulose.

While therefore true lævulosuria, or fructosuria, may be met with it is apparently a rare condition, and in the majority of cases it seems probable that the term is a misnomer, and that the lævrotatory reducing substance that occurs in the urine is in reality the ketonic acid, isoglucuronic acid, we have described. This is differentiated from lævulose by Borchardt's test, by being precipitated from an acid solution by saturation with lead acetate, and the melting point of the parabromphenylosazone.

DEATH FROM STRANGULATED INTERNAL HÆMORRHOIDS.

By P. LOCKHART-MUMMERY, F.R.C.S. ENG.,
SENIOR SURGEON, ST. MARK'S HOSPITAL; SENIOR SURGEON, THE QUEEN'S
HOSPITAL FOR CHILDREN; HONORARY SURGEON, KING EDWARD VII.'S
HOSPITAL FOR OFFICERS;

AND

M. K. JOSHI, M.R.C.S. ENG., L.R.C.P. LOND.,
HOUSE SURGEON, ST. MARK'S HOSPITAL.

INTERNAL hæmorrhoids are an extremely common complaint, but although they give rise to a considerable amount of discomfort and inconvenience, and even disability, it must be very rarely that they are the direct cause of death. Cases of death from embolism following thrombosis of varicose veins in the leg are not uncommon, but a fatal issue from thrombosis of veins in the rectum is, in our experience, a very rare event. It is obvious that the danger of embolism resulting from thrombosis of the rectal veins is not so serious as when the veins of the leg are involved, for whereas the latter veins drain direct into the general circulation, and consequently the detached portion of clot can reach the heart, in the case of thrombosis of the rectum the embolus is more likely to be in the liver, where it would not have such serious consequences.

A case is recorded in THE LANCET of Sept. 23rd, 1911, by Dr. David A. Alexander of portal pyæmia following thrombosed internal piles. This patient had all the symptoms of portal pyæmia—rigors, ascites, œdema of the legs and abdomen, and a high temperature. The patient was very seriously ill for a period of six months, after which he appeared to recover, only to have a relapse three months later, from which, however, he again recovered. The only cause for the portal pyæmia that could be found was a limited tract of thrombosis in the hæmorrhoidal veins.

The following case, which was under our care at St. Mark's Hospital, is evidently of a similar nature, but unfortunately ended fatally. Although we think there was portal pyæmia in this case it was not so marked as in Dr. Alexander's case. The patient died apparently from septicæmia, the result of extensive gangrene of the rectum and neighbouring tissues, but had he survived longer we have very little doubt that the typical abscesses in the liver would have been evident. The only treatment which would appear to have given the patient any chance of recovery was an early colotomy, which would have enabled the bowel to be kept clear of fæcal material. It was, however, obviously unjustifiable to perform colotomy for thrombosed veins in the rectum, and by the time it was obvious

that the whole of the rectum was gangrenous it was too late for this method to have had any chance of success, while the patient was certainly too ill to undergo any operation. The following are the notes of the case.

The patient, a man aged 43, was admitted to St. Mark's Hospital on Nov. 14th, 1914, for internal piles. He stated on admission that he had suffered from internal piles for about 25 years, and that of recent years the piles had prolapsed readily when he walked or on the least exertion, and that they had to be replaced. There had also been considerable bleeding at times. Within the last few years he had had "several attacks of piles," which had necessitated his remaining in bed for some days. The piles had evidently become strangulated during these "attacks," and he had been unable to replace them.

The patient was very much afraid of an operation, and he had put off coming to the hospital for a long time on this account. A severe attack of strangulation of the piles, which had occurred two days before his admission, had finally brought him to the hospital, and on admission he was suffering from strangulation of several large piles. He was very anæmic and seemed ill and in obvious pain. His skin was of a waxy colour; there was considerable puffiness beneath the eyes, and slight œdema of both feet. The lips and ends of the fingers showed a considerable degree of anæmia. There were a number of large varicose veins on the back of both thighs. The patient was very short of breath, apparently from anæmia. Examination of the chest showed slight œdema of both lungs. The heart was somewhat dilated and there was a well-marked hæmic bruit. His liver was slightly enlarged. Examination of the urine showed no albumin or sugar. Examination of the rectum showed a good deal of swelling round the anus and several large prolapsed hæmorrhoids, which were thrombosed and of a dark, bluish colour. Examination was very difficult as the parts were exceedingly tender. He was therefore examined under an anæsthetic, and it was then found that not only were the piles thrombosed, but that all the veins of the rectum appeared to be involved for some two inches up the bowel. The whole of the plexus of veins in the lower part of the rectum was thrombosed and swollen. It was quite impossible to do anything of an operative nature, or even to replace the piles.

The patient was sent back to bed and treated with hot fomentations, &c., to try to reduce the swelling. Instead of improving the condition became worse. Five days after admission there were signs of sloughing of the rectum, and an acute inflammatory swelling began to be evident behind the anus. This was incised, and a great deal of foul serum escaped. Two days later a swelling occurred on the left side of the anus and had to be incised. The whole of the rectum at this time was gangrenous for some four or five inches. The patient had lost all control; he was suffering from almost continuous diarrhœa and was very ill. The pulse-rate was 110, the temperature fluctuating between 99° and 101° F. He also began to complain of severe pain in the abdomen.

On the sixteenth day after admission a slough 1½ inches wide and 4½ inches long, which appeared to consist of all the coats of the rectum, came away. The whole of the buttocks and perineum at this time was œdematous and in a sloughing condition. Examination of the urine showed no albumin or pus. The patient was very seriously ill. During the third week the patient was very tender over the liver and complained frequently of abdominal pain. There were a number of large dilated veins on the abdominal wall and extensive œdema of the lower limbs. The temperature was still fluctuating, but there were no rigors. There was still severe diarrhœa in spite of all treatment. Two severe hæmorrhages occurred at the end of the third week, and the patient died two days later, apparently from septicæmia and general weakness.

Complete gangrene of all the coats of the rectum as the direct result of thrombosed internal piles seems to us a sufficiently rare condition to be worth recording. We are of the opinion that the condition was rendered possible by the secondary anæmia from which the patient was suffering.

A NOTE ON THE TREATMENT OF GUNSHOT WOUNDS OF THE FEMUR.

BY CUTHBERT WALLACE, M.B., B.S. LOND.,
F.R.C.S. ENG.,

SURGEON TO ST. THOMAS'S HOSPITAL, LONDON, AND MAJOR, R.A.M.C.,
BRITISH RED CROSS HOSPITAL, NETLEY.

A LITTLE time ago Mr. B. C. Maybury and myself devised a modification of Thomas's knee splint with the idea of producing powerful extension of the leg during the process of plating fractures of the femur or tibia. When the Red Cross Hospital at Netley was opened the difficulty of adequately treating compound fractures of the femur was soon apparent. The chief difficulty was in maintaining extension and at the same time providing for efficient dressing and (possibly more important) the comfort of the patient. It was determined to try this modified Thomas's splint. The result more than came up to expectations, and cases which arrived with bad wounds and suffering great pain during the process of dressing were soon put at their ease and improved rapidly. In addition to this, some cases which were admitted six weeks after the injury with 3 inches of shortening were soon restored to their normal, or nearly normal, length, and union in a good position resulted.

A short description of the splint (Fig. 1) may be of service to those in charge of other hospitals. The

FIG. 1.

The splint unapplied. Shows the method of obtaining extension by means of a pin. Note the wire fastened by rings to the pin and passing over the pulleys in the transverse bar that carries the footpiece. The traction screw is longer than is now used.

splint as made consists of the original Thomas's crotch ring with a lateral diameter of 9½ inches. The two side pieces are made of mild steel, are parallel, and 8 inches apart. Sliding on these parallel side pieces are two transverse bars. The upper one is fitted with an ordinary footpiece. The lower one is perforated to accommodate a large machine-cut screw. The top of the screw runs in a collar in the transverse footpiece.

The process of application is as follows. The ring is slipped over the foot and adjusted in the ordinary way, care being taken that the inner and back part of the ring gets a bearing on the tuber ischii. As the ring is rather large this is ensured by putting a pad on the outer side of the thigh. The foot is

then fastened to the footpiece by a stirrup extension or a leather anklet, or by webbing embedded in plaster put on over wool wrapped round foot and ankle. The limb is supported in the splint by the two parallel bars in the same way that is usual in the Hodgen splint. The lower transverse sliding piece is then fixed to the two parallel

bars by screws provided for the purpose, and extension applied to the limb by turning the traction screw. The end of the splint is either rested on sandbags or swung by a chain from a masthead or from the roof of the hut. (Fig. 2.) By

FIG. 2.

The splint applied to a fracture in the lower third of the femur. The splint is slung to the roof of the hut by a chain. Note the small pillow under the outer side of the ring. The man's face is expressive of his comfort.

this means the patient is free to move about in bed within reasonable limits, and the dressing of a posterior wound can be effected without discomfort to the patient by either raising the splint or turning him on one side, the constant steady pull of the screw preventing any undue shifting of the limb and consequent pain to the patient. If the limb tends to sag when the patient is turned on his side it can be prevented by loops of bandage fastened to the uppermost bar. (Fig. 4.)

In those cases in which it is impossible to apply the stirrup extension, either because of the state of the skin or from the presence of wounds in the leg, a pin can be driven through the lower end of the femur and the extension applied by a chain or thick picture wire, which runs from one end of the

FIG. 3.

The splint applied to a fracture in the middle of the femur. A pin has been driven through the bottom of the shaft of the bone and extension produced by a chain. The man's foot had been injured by a bullet, so that a strapping extension could not be applied.

pin down to the transverse footpiece over two pulleys let into this, and up again to the opposite end of the pin. The use of the pulleys is to allow

the strain on either side of the limb to be equal, which it is difficult to ensure if the ends of the pin are fastened to the corresponding ends of the transverse footpiece. (Figs. 1 and 3.)

The distance between the parallel bars ensures the easy application of the dressing, and also enables an operation to be performed while the limb lies stretched in the splint. If relaxation is required this can be obtained by reversing the foot screw, and then when extension is required to get the ends in position the screw can again be tightened. The essential part of the splint is the screw, and no other method which has been tried produces a like amount of extension with so little discomfort to the patient.

This splint has been made by Messrs. Allen and Hanbury, of Wigmore-street, London, W. The cost is somewhat heavy, but I do not think it is out of proportion when the results obtained by the splint are considered. In addition, the expenditure is a capital one, and when a number of splints are in hand they can be passed from one

FIG. 4.

Shows the patient turned on his side for dressing a posterior wound (represented by a black piece of paper). Note the small cushion under the junction of the side bar and crotch ring. The limb is kept from sagging by means of loops of bandage passing round the limb and fastened to the upper side bar. They cannot be seen as they are hidden by the slings.

case to another, and even sent across the water to accommodate other people in their transit to this country. A man once in this splint can be moved with very little discomfort, and constant extension of the limb is maintained in spite of the inevitable movement from bed to stretcher which the wounded have to undertake in the process of removal to the base. If one type of splint is to be used for all cases, which can well be done, it is necessary to have the side bars 54 inches long in order to take the limb of a 75-inch man. A 66-inch man wants side bars 43 inches long. There is no disadvantage in having the long splint except that it sticks over the end of the bed. I am, however, having some splints made so that side bars of different lengths can be screwed into the crotch ring. This arrangement has the advantage that the splint can be packed flat. It would also be possible to have one traction-screw attachment for many splints if the transverse foot bar was provided with fastening thumb-screws.

A number of these splints have been provided by the British Red Cross Society and are now in use at this hospital.

The British Red Cross Hospital, Netley.

TYPHOID AND PARATYPHOID INFECTION IN RELATION TO ANTITYPHOID INOCULATION,

TOGETHER WITH REMARKS ON THE IMPORTANCE OF THE USE OF PROPHYLACTIC PARATYPHOID INOCULATION.¹

By GEORGES DREYER, M.A. OXON., M.D. COPENHAGEN, PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF OXFORD, HONORARY CONSULTING PATHOLOGIST TO THE THIRD SOUTHERN GENERAL HOSPITAL;

E. W. AINLEY WALKER, M.A., M.D. OXON., LECTURER IN PATHOLOGY IN THE UNIVERSITY OF OXFORD, HONORARY ASSISTANT CONSULTING PATHOLOGIST TO THE THIRD SOUTHERN GENERAL HOSPITAL;

AND

ALEX. G. GIBSON, M.D. OXON., F.R.C.P. LOND., LECTURER IN MORBID ANATOMY IN THE UNIVERSITY OF OXFORD, CAPTAIN R.A.M.C. (T.), PATHOLOGIST TO THE THIRD SOUTHERN GENERAL HOSPITAL.

At the present time when the prophylactic value of antityphoid inoculation has been fully recognised by the authorities, but is still vehemently opposed in certain quarters, it may prove not only of interest, but perhaps also of considerable value, to record briefly the results of observations made on patients in the Base Hospital at Oxford.

In the light of these observations we wish to emphasise, firstly, the extreme importance of classifying *all* cases returned as cases of "enteric" fever in accordance with the results of detailed bacteriological examination, particularly as regards the precise and careful differentiation between *B. typhosus* and *B. paratyphosus*. For if this be not done a large number of cases of paratyphoid fever are likely to be returned as cases of "enteric." The consequence will be that the statistics regarding the protective value of antityphoid inoculation will become seriously vitiated.

Secondly, we wish to urge again the importance of making prophylactic inoculations against certain other bacterial infections, some of which have already appeared during the war. And on the present occasion we refer particularly to paratyphoid infections, which seem to be occurring with considerable frequency, both in inoculated (antityphoid) and uninoculated individuals. The prophylactic paratyphoid inoculation suggested can readily be effected simultaneously with the antityphoid inoculation by using a mixed vaccine, and, so far as the evidence goes, this procedure does not lead to any notable increase in the severity of the reaction produced.

The Diagnosis.

The agglutination test is the quickest method of diagnosis. Blood cultures and cultures from the urine and faeces will usually enable the observer to isolate the micro-organism where opportunity exists for carrying out repeated examinations. But under war conditions the agglutination method is the one on which reliance must be placed. Accurate differential diagnosis, however, can only be obtained by routine testing of the serum of the patient against the three micro-organisms, *B. typhosus* and *B. paratyphosus* (A) and (B), in parallel series of observations, and by always determining the *maximum* dilution of the serum in which agglutination takes place. Individuals who have been inoculated with antityphoid vaccine within a period of some months or even years will give a high agglutination titre against

¹ The expenses of this work have been defrayed out of a grant received from the National Medical Research Committee.

B. typhosus. Whether they are suffering from active typhoid infection or not can only be determined by repeating the agglutination test at intervals in order to ascertain whether the titre of agglutination shows marked changes or remains practically constant. Such changes are in any case of greater importance in the diagnosis than is the absolute degree of agglutination. They can only be detected with certainty by making use of a standard culture of killed typhoid bacilli and employing the macroscopic method of determination, which is both simpler and more reliable than the microscopic.

A standard culture is readily prepared by the method previously described by one of us (G. D.).

The bacillus (*B. typhosus*, *B. paratyphosus*, &c.) is grown for 24 hours at 37° C. in large flasks in a peptone veal bouillon which has been sterilised in the autoclave at 115° C. for not more than 15 minutes. The culture must be made from a young bouillon culture of a typhoid bacillus which has been subcultivated daily in bouillon, preferably throughout several weeks. At the end of 24 hours the flasks are well shaken and 0.1 per cent. of commercial (40 per cent.) formalin is added. They are again shaken and placed in cold store at about 2° C. At intervals on the same day and on subsequent days for four or five days the flasks are again thoroughly shaken in the cold store. After three or four days they will always be found to be absolutely sterile. The bacterial suspension is subsequently diluted with sterile normal saline solution (containing 0.1 per cent. of formalin) to a standard opacity. Should it happen that the suspension is not entirely homogeneous it is filtered through sterile cotton wool and bottled for use in sterile vessels, either sealed or corked.

The standard culture has the following advantages: (1) It is sterile; (2) it is as sensitive to agglutination as the fresh culture, or even more so; (3) it keeps unchanged almost indefinitely if stored in a cool and dark place; and (4) it renders all observations strictly comparable. For the present purpose the agglutination test is made with the patient's serum against *B. typhosus*, *B. paratyphosus* (A), and *B. paratyphosus* (B) simultaneously in parallel experiments.

Method.—Place 15 small narrow sedimentation tubes in a stand in three rows of 5 each. With a proper dropping pipette measure out into a test-tube 54 drops of tap-water. Dry out the pipette and with it add 6 drops of the serum to be examined, giving a dilution of 1 in 10. Wash out the pipette carefully.

In tube 1 of each row place 0 drops of tap-water.

"	2	"	5	"
"	3	"	8	"
"	4	"	9	"
"	5	"	10	"

Dry the pipette and use it to add—

To tube 1 in each row 10 drops of the serum dilution (1/10).

"	2	"	5	"
"	3	"	2	"
"	4	"	1	"
"	5	"	0	"

Wash the pipette carefully, and then add to each tube in row 1 15 drops of standard *B. typhosus* suspension, to each tube in row 2 15 drops of standard *B. paratyphosus* (B), and to each tube in row 3 15 drops of standard *B. paratyphosus* (A). Shake each tube thoroughly in order from right to left (beginning with the weakest dilution). Place in the water bath at 55° C.

In tube 1 the serum acts in a dilution of 1 in 25.

"	2	"	"	"	1 in 50.
"	3	"	"	"	1 in 125.
"	4	"	"	"	1 in 250.

Tube 5 without serum is the control against spontaneous agglutination.

Higher dilutions are followed out in a similar manner, if the limit of agglutination is not reached within the first series. In inoculated persons who have not had typhoid (or paratyphoid) fever agglutination in a dilution of 1 in 25 justifies

a strong suspicion of typhoid (or paratyphoid) infection. But in such a case the test must be repeated in the course of a day or two. Marked agglutination in a dilution of 1 in 50 or more is nearly always diagnostic of active typhoid (or paratyphoid) infection.

The reaction is completed in about two hours if the tubes containing the dilutions are maintained at a temperature of 55° C. in a water bath (50–55° C.) If left at the room temperature 24 hours must be allowed. Obviously the former procedure is to be preferred.

Inoculated persons may give a very high agglutinating titre, as may be seen in Table I. It is therefore necessary to explain briefly the character of the agglutination curve, and the manner in which the results of successive examinations of the serum are to be interpreted.

In the chart the main curve (broken line) shows the course of agglutination in an actual case of typhoid fever. It is indistinguishable in form from the curve obtained by an experimental inoculation with antityphoid vaccine, though its maximum is lower and its decline more rapid than is usual in the inoculated subject. In the same diagram are given observations on three different patients carried out by the method just described. They illustrate some of the chief points which we wish to bring out.

(α T) exhibits the high agglutination titre (1 in 1500) against *B. typhosus* of the serum of an individual inoculated in September, 1914. It shows no change in three successive observations in the course of six days. During the same period the paratyphoid (B) agglutination (α B) rises rapidly from 1 in 300 to 1 in 700. The agglutination of paratyphoid (A) (α A) is *nil*. Clearly the case is one of paratyphoid (B) infection at an early stage.

(β T) again shows the high and steady typhoid agglutination titre (1 in 1250) of an individual inoculated in August, 1914. Paratyphoid (B) agglutination (β B) during the same period undergoes a striking fall. Paratyphoid (A) agglutination (β A) is *nil*. Again a case of paratyphoid (B) infection.

(γ T) exhibits the steady but now lower typhoid agglutination titre (1 in 250) of an individual inoculated in India as long ago as 1908. His paratyphoid (A) (γ A) and (B) (γ B) agglutination are both *nil*. The patient had neither typhoid fever nor paratyphoid fever.

Apart from the cases of infection occurring in inoculated individuals in which both typhoid and paratyphoid bacilli are agglutinated, other cases occur in the *non-inoculated* where more than one micro-organism is agglutinated by the patient's serum. Here, also, it is necessary to determine the maximum dilution in which each organism is agglutinated, and to follow the agglutination curves in a series of successive observations.

The following statements will afford a sufficient guide in such cases. They are the result of extended general experience, and space does not allow us to present on this occasion the evidence upon which they are based.

1. That bacillus which exhibits the greatest agglutinability (highest agglutination titre) is the infective agent (or the principal infective agent) in the case under examination.

2. If the case is one in which the agglutination of a second micro-organism is due to the presence of *co-agglutinins* the curve of co-agglutination will be found to run parallel to the curve of principal agglutination, but at a lower level.

3. If the case is one of mixed infection with two different organisms their respective curves of agglutination are not parallel, but exhibit totally independent courses, which may even cross one another.

Results.

The results of observations carried out on patients in the Base Hospital at Oxford may now briefly be recapitulated. Table I. gives all necessary details.

Table I. contains all those cases out of the large number examined in course of ordinary routine which yielded positive results in agglutination tests. It will be seen that of these 20 cases suffering from continued fever 8 were diagnosed bacteriologically as typhoid fever and 6 as paratyphoid fever, while the remaining 6 were neither typhoid nor paratyphoid fever.

whether these are merely variants of *B. paratyphosus* (B), or whether the one type is in reality *B. paratyphosus* (A), the other being certainly *B. paratyphosus* (B), has not yet been finally determined. The two individuals had never been in contact before the present illness.

The following are the points of chief importance from the table:—

1. No case of typhoid fever has been found among (antityphoid) inoculated individuals.
2. Of six cases of paratyphoid infection three occurred in (antityphoid) inoculated subjects. Had these cases been returned as cases of "enteric" fever the value of antityphoid inoculation as here exhibited would have been greatly diminished.
3. So far as this limited series of cases goes paratyphoid fever has occurred with equal frequency among (antityphoid) inoculated and non-inoculated individuals. This is in agreement with the finding

CHART SHOWING COURSE OF AGGLUTINATION.

Of the cases of paratyphoid fever one (Case 41), though not inoculated and denying that he had ever had typhoid fever, showed a steady typhoid agglutination of 1 in 1250. Up to the present it has not been possible to isolate the *B. typhosus* either from the urine or faeces of this patient. And we do not know yet whether he is a typhoid carrier or has recently passed through a mild unrecognised typhoid infection followed by infection with *B. paratyphosus* (B).

Cases 62 and 68 in the table are of special interest. Both individuals were inoculated against typhoid fever last autumn. Both have been in France, but never in any other foreign country so far as can be ascertained. In each case the serum strongly agglutinates both *B. paratyphosus* (B) and *B. paratyphosus* (A). The cases are either very striking examples of co-agglutination, or else, as is more probable, they constitute examples of mixed infection. From the faeces in each case paratyphoid bacilli (but no typhoid bacilli) have been isolated. In each case also two distinct types of paratyphoid bacilli are present. But

of Kabeshima and others in long series of observations that antityphoid inoculation affords no appreciable protection against paratyphoid infection.

4. In no case other than cases of active paratyphoid infection has the serum of the patient agglutinated *B. paratyphosus* (B) or (A) in a dilution of 1 in 25, even when the titre of typhoid agglutination was very high. This statement holds good both for (antityphoid) inoculated individuals and for non-inoculated persons suffering from typhoid fever.

5. The typhoid agglutination found in convalescents from typhoid fever is easily distinguishable from that of inoculated individuals. First, it is (with very rare exceptions) of low titre as contrasted with that of persons recently inoculated, whose typhoid agglutination titre remains high

(see table). Secondly, it will always show a definite and measurable diminution of titre in the course of a week or two, while in (antityphoid) inoculated individuals whose titre has by lapse of time fallen to a similarly low level no measurable change will be found within the same period.

Prophylactic Paratyphoid Inoculation.

Paratyphoid vaccines have been studied by Castellani, Cummins and Cumming, Kabeshima and others. This is not the occasion on which to enter into any detailed discussion of their results. But the recent work of Kabeshima affords full evidence, both from animal experiment and from extended observations carried out on the personnel of the Imperial Japanese Navy, of the great protective value as well as the innocuous character of the paratyphoid inoculation. Kabeshima used a mixed vaccine containing equal numbers of

In view of these results it is unnecessary to adduce further evidence of the fact that by the use of a suitable mixed vaccine adequate protection can be obtained against *B. typhosus*, *B. paratyphosus* (A), and *B. paratyphosus* (B).

As regards the reaction produced, Kabeshima states that when the vaccine used is made up of equal quantities of the three micro-organisms concerned, so that the total number of bacilli in the dose does not exceed the usual number present in a dose of antityphoid vaccine, the severity of the reaction (both local and general) is not significantly greater than that following ordinary antityphoid vaccination. Should the question arise as to whether it is better to employ a mixed vaccine of this character or to carry out immunisation against each separate micro-organism separately, it may be stated that the former method is preferable. Obviously it saves time, and it avoids the fre-

■ In these two cases, which are quite recent, it is still uncertain whether the agglutination observed is due to the presence of co-agglutinins or the result of a mixed infection with *B. paratyphosus* (B) and (A).

typhoid, paratyphoid (A), and paratyphoid (B) bacilli. About 12,000 men have been inoculated with the mixed vaccine. The following table from Kabeshima shows the results recorded in five naval hospitals in Japan during the period 1909–1911 after the introduction of inoculation with the mixed vaccine:—

TABLE II.—Kabeshima's Results.

Disease.	Total numbers of cases.	Cases in inoculated subjects.		Cases in non-inoculated subjects.	
		Sick.	Dead.	Sick.	Dead.
Typhoid ...	367	68	5	299	40
Paratyphoid (A)...	289	71	2	218	5
Paratyphoid (B)...	447	0	0	447	0

quent repetition of periods of brief temporary disability. Moreover, there is ample evidence from observations of Jörgensen, Schroeder, Dreyer, and others that in successive immunisation with these micro-organisms the immunity evoked against those organisms which are injected later in the series is less than the immunity obtained when they are mixed together and injected simultaneously, unless a considerable interval is allowed to elapse between the inoculations. And this result is independent of the order in which the different micro-organisms are employed.

Conclusions.

1. It is of the utmost importance that our troops should be protected against paratyphoid infection as well as against the *B. typhosus*. This can readily be done by the use of a mixed vaccine

containing equal quantities of *B. typhosus*, *B. paratyphosus* (B), and *B. paratyphosus* (A). Men already inoculated against *B. typhosus* should also be inoculated against paratyphoid infection, since the antityphoid inoculation offers no appreciable protection against paratyphoid bacilli. The epidemics of typhoid fever reported to be occurring among the belligerents (who are all known to practise antityphoid inoculation) are probably to an important extent epidemics of paratyphoid.

2. Unless all cases of "enteric" fever are properly differentiated into typhoid and paratyphoid infection the statistics regarding the value of antityphoid inoculation among our forces in the present war will be most seriously vitiated. It is probable that the absence of accurate bacteriological diagnosis in the past explains the fact that the statistical results arrived at in our army have not always been so convincing as would otherwise have been the case.

SECTION OF OPHTHALMOLOGY.

Cerebral Degeneration associated with Macular Changes.—Exhibition of Cases and of a Trench Periscope.

A MEETING of this section was held on Feb. 3rd, Mr. PRIESTLEY SMITH, the President, being in the chair.

Dr. F. E. BATTEN and Mr. STEPHEN MAYOU contributed a paper on Cerebral Degeneration associated with Macular Changes, and gave a pathological description of a case. Dr. Batten said that in these cases a curious pigmentation occurred at the macula, and usually also around it, and considerable optic atrophy was also present. Several of the examples of the condition which had been under his care died at Darenth Asylum. He exhibited the pedigrees of two families. In one case the changes in the macula were the last occurrences in the march of degeneration. The brains of these patients did not present any macroscopic abnormality, and they had the usual convolutional pattern, as well as the normal weight and relationship to the cerebellum. The brain and nervous system were examined by several staining methods. There was found to be some degeneration in the medullated fibres; in the cerebellum the myelene was breaking down and degeneration was present in the cells of Purkinje. The most profound change was in the Betz cells; instead of the Nissl granules there was a curious accumulation of fine granules around the nucleus. In the cerebellum were large granular cells not normally seen, and he could not say what their significance was. The most marked change was found in the child who had had the disease longest—namely, for three and a half years. There were marked changes in the fundus, a shrinking of the convolutions, and in some cases the Betz cells were too degenerated to show the vacuolation. This group was similar to the Waren Tay-Sachs cases of amaurotic family idiocy, but occurring at a later age and not race-selective. The disease now described was characterised by progressive blindness, progressive paralysis, and progressive dementia, but changes in the macula were not always present. Mr. Mayou dealt with the pathology of the eye condition. The child he examined had evidently lost all perception of light, but that was not so in all the cases. Immediately after death the eyes were injected and stained. The changes were

confined to the retina, but varied enormously in different parts of the fundus. The principal change was round the macula region. The internal nuclear layers had disappeared altogether, also the rods and cones, and there was some migration of pigment from the retinal pigment cells.—The paper was discussed by Mr. J. H. PARSONS and Mr. TREACHER COLLINS, and Dr. BATTEN and Mr. MAYOU replied.

Mr. A. BERNARD CRIDLAND showed a case of Glass-workers' Cataract in an iron-smelter ("puddler"). He brought the case forward to give an opportunity for the discussion of the type of case in ironworkers in relation to industrial diseases, as these men were not included in the schedule. Considering the number of hours of exposure to the glare of the molten metal, his surprise was that there were not more cases, especially as these men rarely wore protective goggles. He suggested that a more inclusive term should be applied to the cases of cataract so caused, such as "ray cataract."—Mr. C. B. GOULDEN said he had a case now under care in a welder, and he thought an investigation would disclose that the condition was more common among ironworkers than was generally believed. The man who preceded his patient at the work also lost his sight. It was not until quite late that the workers complained, because owing to the dilatation of the pupil they were able to see round the cataract.—Dr. T. M. LEGGE (Home Office) asked as to the proportion of ironworkers afflicted with this condition, as it was necessary in considering the scheduling of diseases to proceed tentatively. In the case of glass-blowers' cataract there could be no question as to scheduling, as he examined the lenses of 513 glass-blowers, and found cortical cataract in 64 in the right eye and 72 in the left.—Mr. PARSONS said that as secretary of a Royal Society committee on the subject he sent many inquiries to ophthalmic surgeons practising in ironworks districts, and the negative replies he mostly obtained led him to the belief that it was the custom for moulders to wear tinted glasses. He asked for further evidence for his committee to continue their investigations.—The PRESIDENT suggested the name "furnace-workers' cataract," seeing that furnace work was common to all.

Dr. E. A. COCKAYNE and Dr. J. ATTLEE showed a case of Amaurotic Family Idiocy in an English child, not Jewish, as was the rule.

Mr. N. BISHOP HARMAN showed a case of Spontaneous Rupture of Cornea in Secondary Glaucoma caused by dislocation of the lens. An injury caused total dislocation of one lens into the posterior chamber, where it was loose. The resulting glaucoma was absolute and vision was lost. The cornea was anæsthetic and the iris quite retracted and immobile. The condition remained so for two years without ulceration of cornea or splitting of Descemet's membrane. Three months later, however, without any further accident, the cornea was split horizontally and membranes prolapsed, the cause having been retrochoroidal hæmorrhage.

The PRESIDENT showed a form of Trench Periscope he had just designed. At the top of a narrow shaft, 6 feet in length, is fixed at an angle of 45° a plane mirror, about 2½ inches in diameter, and an exact counterpart lower down, the distance from the first being adjustable by pegs and holes. Only the top mirror projects above the trench, and this can be largely concealed by a piece of earth. By looking straight into the lower mirror all movements can be plainly discerned without incurring danger.—Lieutenant-Colonel ELLIOTT pointed out how necessary, in order to estimate the distance of the enemy, it was to have the binocular form of periscope.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Fixed Chronic Retroversion of the Uterus.—Exhibition of Specimens.

A MEETING of this section was held on Jan. 15th, Dr. M. J. GIBSON, the President, being in the chair.

Dr. BETHEL SOLOMONS read a paper on Fixed Chronic Retroversion of the Uterus, in which he condemned all such palliative treatments as vaginal douches, tampons, rectal massage, &c., because, firstly, they seldom or never cured; secondly, they kept the patient a chronic invalid for the very

long time which it took even to relieve; thirdly, if the adhesions were so loosened that replacement could be effected and a pessary inserted the patient was in a position very little better than before. He advocated operation in all cases where there were symptoms. Curettage and any necessary vaginal plastic work were done first. The abdomen was then opened, and having treated the adhesions and any adnexal abnormality he suspended the uterus either by Kelly's method or by shortening the round ligaments as the case directed. Where pus was present he drained with iodoform gauze through the posterior fornix and vagina. He considered the abdominal route excellent for drainage, but preferred the vaginal because there was less pain in the removal of the gauze. No opening was left in the aponeurosis; hence hernia was less likely, and the convalescence was usually shorter. If pus was present it should always be taken for culture.—Mr. SPENCER SHEILL said he did not think that all the operations were equally satisfactory; each case had its own indications. All cases with which he had to deal were capable of being replaced; but in a case of markedly adherent uterus he would certainly agree that laparotomy was necessary, though he did not agree that ventral suspension should follow, since the amount of irritation produced by suturing was likely to bring about abortion.—Dr. GIBBON FITZGIBBON said that the drainage of pus tubes was a difficult point. He always felt that by fixing the fundus of the uterus, and then draining the pelvis through the lower angle of the wound, one ran the risk of making the suspension into a fixation, and in these cases, therefore, he thought there was a distinct reason for selecting the Gilliam operation; then, if adhesions were produced they would not cause fixation in the same way as if the uterus was fastened to the peritoneum. He preferred drainage through the abdomen where there was any real necessity for drainage. He had followed up several cases of pregnancy after ventral suspension and had never found that they had any difficulty in pregnancy or delivery, but in some of the cases retroversion recurred three or four weeks after delivery, though this was easily cured by replacement and retention in place by a pessary for six or eight weeks, and then remained in place without any further treatment.—Dr. D. G. MADILL said he did not think that all cases of fixed uterus required operation at all. Most cases that he had seen operated on in Berlin were done by the vagina, and there was no doubt that this method prevented the handling of the intestines, but he thought the abdominal route was preferable. He suggested that these cases were all due to infection, and if any intraperitoneal fluid could be obtained a culture should be taken.—Dr. E. H. TWEEDY said he thought that Dr. Solomons had well described the modern method of treating retroversion. He had never heard of pregnancy in a retroverted uterus being liable to cause rupture of the intestines. Abortion was not unavoidable even in a fixed retroverted uterus, and he therefore thought it a serious step to open the abdomen in such cases whilst the woman was pregnant. He was satisfied that the results were good in ventral suspension, and he had never seen any difficulty in delivery after it. His object was to fix the fundus of the uterus to the bladder, and by that means he obtained an absolutely mobile uterus which was free from danger in pregnancy and delivery. When he heard of relapse after ventral suspension he knew the operation had not been properly performed.—Mr. V. J. McALLISTER said that the exact position and shape of the backwardly displaced uterus were of importance when such a uterus became pregnant. A pregnant uterus which was not only retroverted but also markedly retroflexed would, even in the absence of adhesions, have very little chance of righting itself spontaneously. The presence or absence of uterine descent would guide him, amongst other things, in his selection of an operation for restoring the uterus to its proper position. The Alexander-Adams operation did not lift the uterus to any great extent. It merely drew it forwards. He always ended up these cases by doing this operation provided there seemed to be no reason for attaching the uterus higher up on the abdominal wall. The disadvantage of suspension operations was that, owing to the traumatism of the peritoneum, apart from the question of sepsis, a considerably broader attachment to the uterus might occur than had been intended. Were the uterus very large he would excise portion of its anterior wall.

—The PRESIDENT said that these cases of chronic fixed retroversion were always due to infection, and there were no symptoms which could be associated with the malposition alone. Symptoms attributable to the pelvis were due to the persistence of the pelvic inflammation or to the adhesions. Pain rarely existed if a sufficient interval had elapsed since the infection occurred. The fixation of the uterus and adnexa might cause dyspareunia and difficulty or pain during defecation, but sterility and abortion were the most usual causes of complaint. The relief of fixation of the uterus and adnexa should only be considered when any of the symptoms mentioned were present. Laparotomy should be performed. After the adhesions were divided, and salpingostomy performed in cases of sterility, the round ligaments should be shortened. When symptoms due to the inflammatory condition persisted or recurred after a sufficient interval from time of infection in spite of thorough expectant treatment, as was most likely in gonorrhoeal cases only, removal of the uterus, tubes, and ovaries gave the best results.—Dr. SOLOMONS, replying, said that he made it a rule if any pus could be obtained to take it for examination. He always followed Dr. Tweedy's teaching never to operate on fixed retroversion if there were no symptoms, but it seldom happened that patients consulted him if they had no symptoms. One should choose the operation which best suited the case. He did not agree that when a ventral suspension was performed it went back afterwards. It did not go back unless the operation was badly performed.

The PRESIDENT showed a Tumour from a patient, aged 47 and unmarried, complaining of uterine hæmorrhage every third week. Otherwise she was in good health, and was able to do her work, which entailed much cycling. The abdomen was found fatty and distended, but flaccid and tympanitic all over. There was no difficulty in palpating a fibroid uterus bimanually, but when the abdomen was opened a large thin-walled flaccid cyst, obviously subperitoneal, was found between the layers of the right broad ligament. The intestines were adherent to it. The peritoneum was divided between some of the coils of adherent intestine and the cyst shelled out. The fibroid uterus was then removed with the cyst *en masse*. The patient made a good recovery.

The PRESIDENT also showed a specimen removed from a patient, aged 35, unmarried. She felt perfectly well, but had noticed the abdomen increase in size three months previously. The tumour was impacted in the pelvic cavity, which it filled completely, and above the pelvic brim it swelled out into an enormous growth. There was no history of bleeding or pain, and only occasional difficulty in emptying the bladder. The uterus was found above the pelvic brim and crowded over to the right side; it was atrophied, and there were two small subserous fibroids in the fundus. There was difficulty in removing the tumour, which was growing from the left side of the uterine body and under the broad ligament. The huge cavity which was left was drained through the vagina, covered over, and the uterus left behind.—Dr. TWEEDY said he did not think the second specimen was a myoma at all. He recalled two similar specimens which subsequently proved to be retroperitoneal lipomata. The condition had never been diagnosed before operation.—Dr. SOLOMONS said that fibromyomata of the broad ligament had been reported springing from the uterus and from the subperitoneal muscle fibres of the broad ligament.—Mr. SHEILL thought the shape of the specimen and the manner in which it adapted itself to the pelvis were in favour of lipomata.—Dr. MADILL, referring to the first specimen, asked if any remnant of ovary or uterus was found. In connexion with the second specimen he suggested that it was a myomatous tumour.—Mr. McALLISTER said from the way in which the tissue cut he felt satisfied that it was a soft fibroma. There was also an absence of the coarsely lobulated appearance so characteristic of a lipoma when cut into after hardening.—Dr. R. J. ROWLETTE remarked that the observations of the operator at the time of operation would of itself help to decide whether the tumour was a retroperitoneal sarcoma or not. From the small amount of cut tissue to be seen he thought it looked more like a fibroid. Referring to the first specimen, he said there was a very unusual blending of the cyst and the myoma. He recollected Dr. Tweedy's specimens, and in both cases the tumour was higher up than in this case.

Mr. SHEILL showed photographs of a child born with an unusual frænum between the upper maxillary bone and the lip. It was not considered of great consequence at the time and was left, but as the child grew older it grew rapidly, and at the time of the development of the teeth he had to cut the frænum, which came level with the tips of the two central incisors. He suggested that an epithelial inclusion had been pressed out through the two mesial nasal processes.—Mr. G. P. MOORE, speaking from the dental surgeon's point of view, said that the condition was better dealt with early, as when it was not treated until after the eruption of the permanent teeth it caused excessive space between the centre incisors and often great irregularity and projection forward of the incisors, which was difficult to cure and very unsightly.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Marsupialisation of Degenerated and Infected Fibroids.—Rupture of Uterus with Fatal Result.—Exhibition of Specimens.

A MEETING of this society was held in Manchester on Jan. 15th, Dr. J. H. WILLETT (Liverpool), the President, being in the chair.

Dr. W. E. FOTHERGILL (Manchester) mentioned two cases of Large Fibroids he had met with—one in 1899 and the other in 1914—whose adhesions were so dense and so universal that the growths could not be removed. In each case the degenerated tumour was scraped away by hand through the abdominal incision until nothing but a thin shell was left. The capsule was then stitched to a portion of the abdomifal incision. In one case the cavity was packed with gauze, while in the other double drainage was provided by a long rubber tube, one of whose ends passed down into the vagina while the other opened through the abdominal wound. The latter method gave the better result as to rapidity of healing.

Dr. FOTHERGILL also described the injuries in a case in which the medical attendant performed version, and subsequently discovered a complete Rupture of the Uterus. The patient was aged 40, and the labour was her tenth at full term. She had also had five abortions. On admission to hospital the pulse-rate was 144, and the patient had lost so much blood that she was gasping. The abdomen was opened and its wall above the pubic symphysis was seen to contain extravasated blood. The peritoneum was torn from the pubic symphysis in front to a point near the lower pole of the right kidney. The bladder was exposed, with the exception of its trigone and the lower part of its left lateral aspect. The ureter and the blood vessels on the right side could not be traced through the mass of blood clot and lacerated tissue which occupied the right side of the pelvis and lower abdomen. The cæcum and appendix were torn from their bed. The uterus was quickly removed and the peritoneum was drawn together. A gauze drain was left *in situ* for 48 hours. The patient did well for four days, but suppuration occurred which was confined to the pelvis, and she died on the sixth day. The records show that this was the seventeenth case of serious rupture of the uterus treated by abdominal hysterectomy at St. Mary's Hospitals, Manchester, the first having been done by Dr. Walls in 1905. Of these 17 cases, 12 were successful, and these 12 women doubtless owed their lives to the removal of the uterus. Suture of the rent was not enough in serious cases of uterine rupture.

Dr. W. K. WALLS (Manchester) exhibited the following specimens: 1. A Rupture of the Pregnant Uterus through an Old Cæsarean Section Scar removed from a patient, aged 30, who had had three previous Cæsarean sections. The patient was seven months pregnant when sudden severe abdominal pain commenced, followed soon after by general collapse. The abdomen was opened and the peritoneal cavity was found to be full of blood, which was oozing from the top of the old Cæsarean section scar in the uterus. Supravaginal hysterectomy was performed, but the patient died from shock the same evening. 2. Cæsarean Section for Accidental Hæmorrhage oozing from the Scar of a previous Cæsarean Section. This patient had had one previous Cæsarean section and was within ten days of full-term pregnancy for the second time when she commenced with symptoms of accidental hæmorrhage. For

this reason Cæsarean section was performed, during which the abdominal cavity was found to contain a large quantity of blood. This was oozing from the lower part of the old Cæsarean section scar in the uterus, which was very broad and thin and would probably soon have opened out along its whole length. Supravaginal hysterectomy was performed, and the patient made a good recovery.

Dr. W. FLETCHER SHAW (Manchester) exhibited a specimen of Spontaneous Rupture of Old Cæsarean Section Scar in a Full-term Pregnant Uterus. This patient had had one previous Cæsarean section and was within a week of full term in her second pregnancy, for which Cæsarean section was again going to be performed, when severe abdominal pain commenced during the night while the patient was in bed. Six hours later she walked to the hospital, arriving in a collapsed condition, still complaining of severe pain in the middle line of the abdomen from the umbilicus to the pubes, and this portion of the abdomen was very tender. The pulse was fluttering and uncountable, and the temperature subnormal. The abdomen was opened and the old uterine Cæsarean scar then found to have completely opened up, so that the child was delivered without any enlargement of this wound being required. The placenta was on the anterior surface of the uterus, and plugged the wound. At the time of operation no further bleeding was taking place, but the lower part of the abdominal cavity was filled with blood clot. Supravaginal hysterectomy was performed, and the patient made a good recovery.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—

A pathological meeting of this society was held on Feb. 5th, Mr. Aslett Baldwin, the President, being in the chair. The President showed specimens of: (1) an Innocent Tumour of the Submaxillary Gland which simulated malignant disease; (2) Stricture of the Transverse Colon; and (3) (with Dr. Reginald Morton) radiographs of a Large Ureteral Calculus in a youth aged 15½ years. One of the radiographs was taken after collargol had been injected up the ureter. This completely surrounded the calculus and thus verified its position. At the operation the ureter above the calculus was found dilated to about the size of the small intestine.—Mr. McAdam Eccles showed specimens of (1) Gall-stones (a) causing obstruction, (b) loose in dilated gall-bladder, (c) blocking the cystic duct; (2) Vermiform Appendices showing (a) mucocele, (b) papilloma, (c) perforation protected by omentum, (d) colloid carcinoma, (e) diverticulum from the side opposite the mesentery.—Dr. E. A. Saunders and Dr. R. R. Elworthy showed specimens of two cases of Congenital Disease of the Heart with death from broncho-pneumonia.—Dr. Elworthy also showed a number of interesting pathological specimens, including one of Aneurysm of the Posterior Communicating Arteries, and also one to illustrate Recurrent Laryngeal Palsy in a child aged 2 years.—Dr. Saunders and Dr. Morton showed radiograms illustrative of Progressive Stages of Early Pulmonary Tuberculosis in Children; also radiograms showing the Lung Picture in Early Pulmonary Tuberculosis before and after sanatorium treatment.—Dr. H. J. F. Simson showed specimens of Ovarian Cysts, Uterine Carcinoma, and the Fallopian Tubes from a case of Tuberculous Peritonitis.—Mr. N. Bishop Harman showed specimens illustrating (a) Spontaneous Rupture of the Cornea in Secondary Glaucoma caused by Dislocation of the Lens; (b) Panophthalmitis, due to hatpin wound; and (c) Sympathetic Ophthalmitis following subconjunctival rupture of the sclerotic.—Dr. Saunders also showed specimens of the Indian Leech, recently introduced by the efforts of Professor A. E. Shipley, to counteract the present shortage of the usual supply from the continent.—Commenting on the President's specimen of intestinal obstruction, Dr. Seymour Taylor pointed out that while obstruction due to malignant disease was placed among the chronic forms, rightly in most cases, clinical experience showed that malignant obstruction might be acute, and cases occurred in which the sufferer was entirely ignorant of the grave disease he had until some urgent condition called for the advice of his medical attendant.—The President and Mr. F. G. Lloyd referred to the very interesting series of specimens shown by Mr. McAdam Eccles, some of them almost unique. Particular mention was made of the size to which gall-stones and other concretions could reach without giving rise to any serious symptoms, and conversely how frequently a comparatively small

calculus called for immediate operation to save life.—Colonel T. H. Hendley, I.M.S., commented upon Mr. Bishop Harman's specimens, and cited a case of sympathetic ophthalmia following perforation of one eyeball by a single pellet of shot.—Dr. Saunders having been called away, Dr. Morton referred to the skiagrams he had made of the cases of early pulmonary tuberculosis in children. These were from children in whom the physical signs were either entirely absent or so few and slight as to make it impossible to form any definite opinion on their condition. The X ray appearances in all of them were quite definite, and such as are found in cases proved to be tuberculous. Considering the importance of an early diagnosis in indicating the proper treatment at the earliest possible time, he urged the advisability of a radiographic examination of the lungs in those children who, while presenting no definite signs of any particular disease, were not thriving and enjoying life as others of the same age. With regard to the lung picture before and after sanatorium treatment, here as elsewhere once the bacillus had obtained a footing for a definite period of time a permanent mark was left as evidence of the unwelcome visitation. The markings in the lungs after successful treatment followed the same general plan as before; some of the finest "mottling" might have disappeared, but the chief difference might be described as one of diminished contrasts in the picture.—Mr. Lloyd was not so sure as to how much reliance was to be placed on the X ray findings, and considered that while the radiographic method might be a useful adjunct to other methods of diagnosis it had by no means superseded them. At the same time he paid a tribute to the advances made in radiography in recent years.

Reviews and Notices of Books.

Pharmacology, Clinical and Experimental.

By Dr. HANS H. MEYER, of Vienna, and Dr. R. GOTTLIEB, of Heidelberg, Professors of Pharmacology. Authorised translation into English by JOHN TAYLOR HALSEY, M.D. With 65 text illustrations, 7 in colour. London and Philadelphia: J. B. Lippincott Company. 1914. Pp. 604. Price 25s. net.

TAKEN in its widest sense experimental pharmacology is the relation of organisms under chemically changed conditions of environment, and must therefore be regarded as a department of biology. The authors treat the subject from two aspects, organotropic—i.e., the action of drugs on function—and etiotropic, their action in disease. The pharmacology of the following systems is dealt with in succession—motor nerve endings, central nervous system, sensory nerve endings, the vegetative system, eye, digestion, genital organs, circulation, respiratory organs, the renal function, sweat secretion, metabolism, muscle, blood, temperature, and inflammatory phenomena. A special chapter discusses pharmacological effects on the causes of disease and deals with antiseptics, anthelmintics, and antitoxins, acquired immunity, serum therapeutics, the serum treatment of tetanus and diphtheria, and bacteriolysis. The last chapter is devoted to the conditions necessary for the action of medicaments, such as solubility, concentration of the drug in the blood, the condition of the organism itself to be acted on, antidotes and antagonism, and the various refractive or hypersensitive conditions that are included under the term idiosyncrasy—not forgetting anaphylaxis.

In the chapter on motor nerve endings curare is very fully dealt with—although it is but little used in medicine—because it gives such a good example of localised action, as well as affords a typical instance of how the action of a drug can be studied. As to the pharmacology of the central nervous

system, drugs may either increase or diminish its functions, but cannot change these functions qualitatively. This section is treated in a lucid, practical, and even masterly manner. First those drugs that excite, such as strychnine, and then those that depress and paralyse central nervous functions are discussed, special attention being given to the morphine group. Morphine itself occupies a peculiar position owing to its striking and wonderful property of subduing pain, although morphine does not diminish the excitability of the brain and cord to the same extent as such narcotics as alcohol and the chloroform group. Special attention is drawn to its action on the respiratory centre. Alcohol and inhalation anaesthesia, including ether and chloroform, are next considered. Chloral and its cumulative perils are set forth, while trional, veronal, and their allies are discussed and their uses and dangerous effects commented on. The well-known theory of narcosis of Meyer and Overton is elaborated and the importance of lipoids is emphasised. Local anaesthesia is fully treated, most emphasis being laid on cocaine and its allies. There is a good coloured plate illustrating the sympathetic nervous system. The monograph on the eye in relation to drugs is concise and practical. The pharmacology of the digestive tract is treated discreetly in about 60 pages, while 100 are given to the circulatory organs. The treatment of the action of digitalis is particularly good.

We have instanced only a few points why we cordially commend this treatise to all interested in the progress of pharmacology in relation to scientific medicine. Much praise is due to the translator, who is professor of pharmacology, therapeutics, and clinical medicine in Tulane University.

A History of the Indian Medical Service, 1600-1913.

By Lieutenant-Colonel D. G. CRAWFORD, Bengal Medical Service (retired list). London: W. Thacker and Co. 1914. Pp. 529 + 535. Price 28s. net.

IN two handsome octavo volumes there has at length appeared a detailed history of the Indian Medical Service worthy of its subject and fit to rank with any of the regimental histories of the British army hitherto published. Of the 45 chapters the first 12 are concerned with the early history of European medicine in India before the formation of the Bengal Medical Service in 1763. The next 15 describe the chief features in the official history of the three separate medical services in Bengal, Madras, and Bombay, and also give a large amount of information on many matters of professional and social interest. Chapters XXVIII. to XXXIV. give in more detail special records of distinguished medical men of the Indian establishment; and in the following 10 chapters are discussed the recent history of the Service and medical matters in India generally.

His brother officers, and all concerned with medical practice and education in the East, are indebted to Colonel Crawford for his researches and for the clear manner in which they have been presented to the reader. Many curious sidelights are thrown on old-time Anglo-Indian life which will make the book interesting to the lover of the past; but its main purpose has been to record the gradual evolution of the present homogeneous and uniform service from the small beginnings of the seventeenth century, showing how in the true British way mistakes are made, and order and success

eventually attained by the means of these mistakes. As the author quotes from Emerson: "They builded better than they knew." We may mention that each chapter has an appropriate poetical heading, which relieves the somewhat dry recital of records and regulations. We regret to learn that the time-honoured story of the cure of Shah Jehan's daughter by Gabriel Boughton, and the consequent bestowal on him of a grant in favour of the Honourable East India Company, has no foundation. The Bengal Medical Service was founded in 1763; on two occasions, in 1766 and 1796, it was divided into two separate services, military and civil, and each time the separation was found to be impracticable, and the two branches were again united. Administrative officers of the Army Medical Department were first appointed to India in 1825, and friction appears soon to have arisen between the two services.

Colonel Crawford is doubtful as to the suitability of the present system of instruction for I.M.S. officers. He considers that Indian diseases would be better studied in India, in the large hospitals of the Presidency towns, which provide an extensive field for research, and are now well equipped with modern appliances. The recent history of the Service is treated of in detail as regards scientific, military, civil, and professional matters. The author believes that the regimental hospital system will be abolished in the Indian as it was in the British Army. It "has outlived its usefulness." A closer relationship between the military and civil branches is desirable. How it is to be brought about is not yet apparent. Professor Maclean's Christian names were William Campbell, not William Charles; G.C.B. stands for Grand Cross, not Grand Commander, of the Bath (p. 210). A list of Fellows of the Royal Society in the Indian Medical Service would be acceptable.

Colonel Crawford is to be highly congratulated on the successful accomplishment of his task, while the volumes are extremely well printed and well got up.

Flies in Relation to Disease: Non-Bloodsucking Flies.

By G. S. GRAHAM-SMITH, M.D. Cantab. Cambridge: University Press. 1914. Pp. 389. Price 12s. 6d. net.

WE have already noticed the first edition¹ of this handbook, but the second edition is not merely a reprint with a fresh preface. It is an amended and enlarged replica of the original edition, though appearing only a year later. Even with such excellent assistance as is offered by the *Zoological Record* it is hard to be sure that a bibliography upon a given zoological subject is exhaustive, and the difficulty obviously increases with the length of the list of titles of works given. The author finds 25 pages fairly closely printed necessary for bringing the reader in view of what has been written concerning the muscidæ and other non-biting flies. It is not therefore surprising to learn that Dr. Graham-Smith has found that he neglected a few memoirs in the earlier edition. These are duly intercalated in their proper places in the present revised bibliography. The work to which these papers refer is, however, separately dealt with in an appendix, together with more recent work which has appeared since the first edition of the book was published. This appendix occupies nearly one hundred pages, and is a testimony to the immense

output of scientific work nowadays. It appears from an inspection of the lists of titles that a large amount of this collected work is from British sources; much also is American, much French, and rather less Italian. The Germans do not bulk so largely.

Gonorrhœa and its Complications in the Male and Female.

By DAVID WATSON, M.B., C.M. Glasg., Surgeon Glasgow Lock Hospital; Dispensary Surgeon for Venereal Diseases, Glasgow Royal Infirmary, &c. With 72 illustrations and 12 plates, 9 of which are in colours. London: Henry Kimpton. 1914. Pp. 375. Price 15s. net.

It is only within recent years that the importance of gonorrhœa has been recognised, even by the medical profession, and still it is regarded as a trivial affection by the general public. It is now acknowledged that there is room for discussion whether it is not on the whole a more serious disease than syphilis, when all its numerous complications and sequelæ are borne in mind. This book contains one of the best accounts that we have seen of this disease and its treatment; it is comprehensive, it is eminently readable, and above all it is extremely practical. The author, while mentioning carefully the various methods which have been employed in treating the different conditions which may occur, explains the grounds on which choice between them should be based. With regard to the use of gonococcal vaccine he speaks very definitely; he says that though he is convinced that the vaccine has a specific power to modify the disease, yet he is equally convinced that as yet we have not worked out the data necessary to enable us to use the vaccine with sufficient control over its therapeutic action to justify its indiscriminate employment.

The absence of references to original papers should be corrected in future issues.

LIBRARY TABLE.

Text-book of Massage and Remedial Gymnastics. By L. L. DESPARD, Member and Examiner, Incorporated Society of Trained Masseuses. Second edition. London: Henry Frowde, Oxford University Press, and Hodder and Stoughton. 1914. Pp. 413. Price 12s. 6d. net.—Those who practise massage require to have a knowledge of a certain amount of anatomy, but it is by no means easy to determine what are the exact limits of the anatomy they should be taught. In this volume we cannot help thinking that the author has included too much, though perhaps this is an error in the right direction. It is surely unnecessary to include in such a work as this details as to the surfaces of the fibula or the origin and insertion of the pectineus muscle. At all events, we may rest assured that very few students of massage ever learn such details as these. Apart from these strictures we have nothing but good to say about this book; the student of massage will find all that he needs in it. The large number of illustrations add to the value of the work; those representing anatomical structures come from "Cunningham's Anatomy."

Essays and Addresses. By the late JAMES CAMPBELL BROWN, D.Sc. Lond., LL.D. Aberd. With a portrait and 22 illustrations. London: J. and A. Churchill. 1914. Pp. 208. Price 5s. net.—We can cordially recommend these essays to the notice of

¹ THE LANCET, March 14th, 1914, p. 756.

students intending to take up chemistry as a profession, particularly in its industrial applications. The late Dr. Campbell Brown, who was professor of chemistry in the University of Liverpool, possessed an intimate acquaintance with the relations of chemistry to the every-day affairs of human life, and at this moment when great opportunities are opening for extending our chemical industries his essays on such subjects as "A French View of German Industries," "What is Technical Education?" "Chemistry as a Profession," "Analytical Chemistry as a Profession," "The Ethics of Chemical Manufacture," come opportunely in this publication. His counsels are good and most interesting in view of the "decadence of English chemical industry" (see ill-informed writers *passim*).

The Midwives' Companion. By FÉLICIE NORTON. London: J. and A. Churchill. Pp. 101. Price 1s. net.—This book is intended for the use of senior students and midwives. In our opinion the author is ill-advised to lay so much stress upon asepsis and to say so little about antiseptics, a much better practice for midwives than any attempt to carry out strict asepsis. We cannot agree with the recommendation of Schultze's method for the revival of a child suffering from white asphyxia, and we entirely disagree with so-called aseptic plugging of the vagina by a midwife for a case of placenta prævia. The author might have been more careful in her revision of her proofs.

Manual of Training for Jungle and River Warfare. London: T. Werner Laurie. Pp. 124. Price 3s. 6d. net.—Major Gordon Casserly, of the Indian Army, has put together in this little book a great deal of useful information. From the medical point of view his advice generally is sound and clearly expressed. Many native terms are used which might have been translated or explained, and it would have been useful if he had stated what are "the usual precautions" to prevent contamination of a water-supply. It is not customary to carry an enema syringe in a "pocket case" (p. 83), and 1 in 100 carbolic acid is not an efficient application to wounds. The preventive measures against malaria might have been given more fully. On practical matters regarding warfare in the jungle and on river banks the book is most useful. It is well illustrated by the author.

The Book of Prescriptions. By E. W. LUCAS, F.I.C., F.C.S. Tenth edition. London: J. and A. Churchill. 1915. Pp. 371. Price 6s. 6d. net.—The enormous number of drugs brought into use since the last edition of this book was printed would have rendered a fresh issue imperative, even in the absence of a new determining cause in an alteration in the list of official drugs. A new British Pharmacopœia, casting out many drugs and absorbing a few fresh articles which have found favour with the medical profession, has led to a revision which is likely to be of great service. As a member of the British Pharmacopœia Reference Committee Mr. Lucas had already done work which has received special acknowledgment, and it may therefore be assumed that he will be a safe guide in many of the pitfalls presented by the new standard. The prescriptions should be frequently consulted by beginners who are anxious to adopt the metric system; they are printed in parallel columns with a formula of familiar appearance on the left hand, and with the equivalent in the metric system on the right. These object lessons will be very useful

to those who wish to move with the times. Information relating to many new unofficial remedies has been included, but there is no indication of its unofficial character; it might have been well to mark such paragraphs with an asterisk or other sign. The list of synonyms on page 15 appears rather antiquated in attempting to encourage mystification. When preparing the next edition with greater leisure it would be well to secure more consistency and to employ the official names and contractions; on the first page it is a surprise to find "hexamethylenetetramine" where the official title "hexamine" should have appeared. We meet with Spirit. Chlorof. and with Sp. Chloroformi, with P. Saponis and Pulv. Saponis, with P. Boracis and Pulv. Boracis. These minor blemishes, however, do not materially detract from the general utility of the book; they are more than counterbalanced by the precision of the text and by the numerous hints to prescribers and dispensers.

MISCELLANEOUS VOLUMES.

NEVER did the British Empire and race stand in more urgent need of the greatest possible excellence in mothercraft than at this present time, when the European nations are engaged in a death struggle. The National Association for the Prevention of Infant Mortality and for the Welfare of Infancy has done well in putting forth, under the title of *Mothercraft* (London: The National League for Physical Education and Improvement. 1915. Pp. 244. Price 3s. net), a course of lectures delivered under its auspices during the winter quarter of last year at the Royal Society of Medicine and Charing Cross Hospital Medical School. These lectures are 16 in number and cover the subject of antenatal preparation of the mother, various forms of infant feeding, the general and special ailments of children, and the establishment and working of infant welfare centres. The medical contributors are Dr. C. W. Saleeby, Dr. Amand Routh, Dr. Harold Waller, Dr. F. Langmead, Dr. Eric Pritchard, Dr. H. C. Cameron, Dr. Ronald Carter, Dr. D. Forsyth, Lieutenant-Colonel E. Roberts, M.B., Mr. Sydney Stephenson, Mr. Macleod Yearsley, Mr. C. E. Wallis, Mrs. Florence Willey, M.D., and Dr. F. J. Allan. Marion Fitzgerald writes on How to Visit Homes, and Miss M. B. Synge adds a chapter on the Clothing of Infants. To the end that the book may be widely read by Englishwomen of all classes it would seem desirable that a much cheaper edition should be published.

An interesting series of lectures on *Science and Religion*, delivered by eminent men of science in Browning Hall, London, during "Science Week, 1914," has recently been published (London: W. A. Hammond, Holborn Hall, E.C. Pp. 138. Price 1s. net). The lectures are as follows: Help from the Unseen, by Sir Oliver Lodge, F.R.S.; the Supreme Intelligence in and above Nature, by Professor J. A. Fleming, F.R.S.; Religion the Crowning Stone of Science, by Professor W. B. Bottomley, F.C.S.; the Witness of Geology to Revelation, by Professor Edward Hull, F.R.S.; Science and the Unknown, by Mr. John Allen Harker, F.R.S.; the Origin of Life, by Professor G. Sims Woodhead, F.R.S.; Religion and Science, their Alleged Incompatibility, by Professor Silvanus Thompson, F.R.S. In these essays the reputed incompatibility between the fundamentals of religion and the facts and principles established by science in its various branches is critically investigated by men of established reputation in the scientific world, who put forward reasons for holding that a study of the material aspect of nature, so far from negating the grounds for a belief in a spiritual substratum and origin, entirely supports such a view. An introduction describes the aim, the speakers, and the meetings, while Mr. J. E. Stead, F.R.S., adds a rider in the shape of a suggestion that religion must be scientific, by which is meant that its further investigation must be conducted by scientific methods. The book contains portraits and brief bibliographical notes of the speakers, and is well worth reading.

The Balkan Cockpit, by W. H. CRAWFORD PRICE (London: T. Werner Laurie. Pp. 369. Price 10s. 6d. net), is a pleasantly written chronicle of the war of 1912-13 between the Balkan Alliance (Bulgaria, Greece, Montenegro, Serbia) and Turkey, together with the ensuing war between the Allies—namely, Bulgaria against the other three. The downfall of Turkey in the first instance and the defeat of Bulgaria in the second are still bearing fruit in the present general European conflict. From a medical point of view the most interesting portion of the book is the account which Mr. Price gives of the admirable paper organisation of the Turkish military medical force and its hopeless breakdown in action. Further, although the Turkish Red Crescent organisation worked well the authorities thereof refused to lend a helping hand to their military brethren, whose hospitals were lamentably understaffed and were without food, medical comforts, bandages, or medicines.

Miss ETHEL C. HARGROVE went to Portugal on the invitation of the Sociedad Propaganda de Portugal as a member of the British International Association of Journalists, and her book, *Progressive Portugal* (London: T. Werner Laurie. 1914. Pp. 276. Price 6s. net), is a brightly written, if superficial, account of what she saw and did there. Portugal, which has been Britain's ally from the time of the Crusades, is a country with a most interesting history. Its climate, architecture, and vegetation are all fascinating and but little known to the majority of British travellers. The recent change of government has apparently been of an awakening nature, and Miss Hargrove points out that the Republic took early steps to reorganise the public institutions, especially the hospitals, which are now being modernised all round. The book is supplied with a map and with numerous illustrations, but we have also noticed an unduly large number of misprints.

Of books for students of the résumé class there are two kinds—those that should be unhesitatingly condemned for inherent defects and those that are not dangerous unless improperly used, and may even serve a useful purpose if used merely to systematise knowledge. To the latter class belongs *Aids to Pathology*, by Dr. HARRY CAMPBELL (London: Baillière, Tindall, and Cox. 1915. Pp. 228. Price 3s. net; in cloth 3s. 6d. net). The third edition of this book contains much additional matter on immunity. A chapter on diseases of the heart has been added, and there is considerable amplification in other directions.

JOURNALS.

British Dental Journal.—The first January issue of this journal contains a paper by Mr. W. Hern on Oral Hygiene and Prophylaxis. After recounting the various conditions giving rise to gingivitis Mr. Hern discusses the most efficient means of keeping the mouth in a state of cleanliness. He seems to think that reliance can be placed upon the use of the tooth-brush, and suggests patterns of brushes to be used as well as the methods for brushing the teeth. He discusses briefly the value of tooth powders, and incidentally does not place much reliance upon the use of antiseptic washes. The discussion on the paper is printed, and many of the speakers obviously thought that the question of oral hygiene and prophylaxis should be approached from rather a broader point of view than that suggested by Mr. Hern—viz., on the broad lines of dietetics and efficient mastication.—Mr. W. H. Gilmour reports an interesting case of fractured teeth from a bullet, the bullet having indentations on both upper and lower surfaces.—Mr. Arthur Underwood contributes a very interesting letter on the question of the scarcity of dental practitioners, and thinks that the cause rests in the unsatisfactory condition of dental legislation.—The issue for Jan. 15th contains an article by F. W. Broderick on The Relation between Calcium Metabolism and Dental Diseases. The author discusses the manner in which calcium is found in the body, and describes how the calcium balance is maintained. He considers that caries is the result of a deficient calcium output, which reduces the alkalinity of the saliva, while he regards periodontal disease as due to calcium saturation, the excess salts being deposited around the necks of the teeth and, acting as mechanical irritants, press the gum's margins away and lay them open to infection. There is a reprint of a lecture by Mr. Howard Mummery on Calcification; also two letters dealing with the question of shortage of qualified dentists.

New Inventions.

VENTILATED ELASTIC STOCKINGS FOR VARICOSE VEINS.

THE medical profession will, I think, be glad to have their attention called to a ventilated stocking which I have recently been employing in cases of varicose veins associated with eczema. In these cases patients often complain bitterly of the almost intolerable itching provoked by the heat inseparable from the use of stockings of solid elastic. The substitution of perforated bandages is but a partial remedy for the drawback, the necessary overlapping of the folds of the bandage neutralising to some extent the effect of the perforation. The intense irritation suffered in an exceptionally severe case of mine prompted me to consult Messrs. Maw, Son, and Sons as to the practicability of constructing an elastic stocking on the principle of cellular clothing. The attempt was made, and made successfully, for I have tried the stocking in a number of appropriate cases and have found that it admirably fulfils the desired purpose of affording support without heat. The stocking, composed of finely meshed silk and elastic, supports the distended veins not less effectually than does a stocking of solid elastic, while permitting free ventilation. For obvious reasons, in cases in which there is discharge it must not be applied until the exudation has ceased. Where economy is an important consideration cotton can be substituted for silk, and, whether made of the one material or of the other, the stocking can be employed with advantage in cases of uncomplicated varicose veins as well as in those in which there is associated eczema.

Harley-street, W.

MALCOLM MORRIS, F.R.C.S. Edin.

THE "STICK" LEG-REST.

THIS ingenious little invention consists of a very stout stick split in halves, the halves being joined by bands of webbing, as shown in the picture. The halves, closed and secured by a thick rubber cap on each end, make a stout walking-stick. When the halves are separated the stick becomes a leg-rest of a very comfortable sort in any position; each half is converted into an adjustable splint, the leg

resting comfortably on the webbing. The length of the stick is 33 inches, so that as a rest the apparatus just fits across the seat of a railway train. The removing the caps to open up the stick is simple, and the caps are very substantial, so that they may not be worn out by use as ferrules. The price of the stick leg-rest is 4s. 6d., and all communications should be made to Mr. George Marshall, Seymour Works, Seymour-place, Bryanston-square, London, W.

BELGIAN REFUGEES UNDER THE INSURANCE ACTS.

—A circular of the Local Government Board addressed to local refugee committees has given explanations as to the position of Belgian refugees towards insurance when they obtain employment in this country. Employers have to pay the same contributions whether they employ their countrymen or Belgians. The refugee in certain circumstances may claim exemption, as may the British subject. The Belgian, if insured, must obtain a card and either join an Approved Society or remain outside, as he may prefer. His benefits from the society will be such as it is in a position to give in return for his contributions. He will, in fact, be in the position of an ordinary foreigner. By joining an Approved Society he will usually become entitled to medical and sanatorium benefits at once, but will not be in the same position as a British subject with regard to other benefits.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 13, 1915.

The Invalid and the Fighting Line.

WE called attention recently to a striking manifestation of patriotism shown by subjects of aortic insufficiency who, while quite aware of the nature of their disability, had nevertheless been found in the fighting line of the French army. A recent report to the Académie de Médecine has shown that this display of heroism has been widespread, incidentally proving that compensation in quite serious cardiac lesions is for a time often very complete. The situation, however, that may arise from the successful attempt upon the part of a physically damaged man to enrol himself in the army as sound may be so serious that while we admire we regret such exploits. And the French army is not singular in providing examples. The experience of the medical men who passed recruits for enlistment in our rapidly created army was, as is known, satisfactory on the whole: it entirely contradicted the more gloomy prognostications of the untiring prophets of our physical decay as a nation, while the summary inspection led to the immediate remedy in many cases of minor evils which in all probability would have otherwise gone unattended, inasmuch as their subjects had finished their school careers before the national system of inspection was in effective order. The good health now maintained in our army is a proof that in physique and stamina there has not been the widespread deterioration which in many magazine articles we were asked to face; while on the other hand the capacity shown by masses of men drawn from every class, varying in age by 20 years, and in many cases not distinguished by external signs of rude health or muscular vigour, to endure the shocks of actual war as well as the strenuous labour of military training, has been surprising. There has, of course, been from time to time sickness in different camps, but by treatment and prevention, by the coöperation of the medical and sanitary branches with military chiefs who understood the importance of hygiene, the health of our troops has been conserved in a wonderful manner. But undoubtedly a certain number of unfit men were accepted. The work of the recruiting medical officers in the first days of stress was done at full speed, and we have all heard of individual cases of recruits whose disabilities for a military life were manifested very quickly. And it was quite well known that the enrolment of some of these men was not due so much to the hurry of the recruiting procedure as to that very spirit of heroism which has been so markedly displayed by cardiac subjects in France.

At the meeting of the Académie de Médecine of Paris M. Ch. FIESSINGER reported some truly remarkable cases in which the subjects of other forms of heart disease showed as much staying power as those suffering from aortic insufficiency. The declaration of war caused, said M. FIESSINGER, the national energies to manifest themselves in an "élan incomparable," and under the stimulus failing organs worked better for a time. Those who had good reason to remain at home ignored medical advice and went to the frontier like the others. M. FIESSINGER referred to 12 cases, in 6 of which the patients were retired officers. The remaining 6 were officers in the army, who would no longer incur the shame of being considered "infirmes" and followed their comrades. The diseases present in these 12 cases were as follows: in 5 affections of the myocardium (myocarditis or renal heart), paroxysmal tachycardia in 1, and valvular disease in 6 (3 cases of mitral regurgitation, 1 of mitral obstruction, and 2 of aortic insufficiency). The treatment usually followed was administration of 1/10th of a milligramme of crystalline digitalin for two or three consecutive days as a prophylactic when the heart was not failing, and the same dose for 10 consecutive days with intervals of four days when there were signs of myocardial failure. As might have been foreseen, the subjects of valvular disease stood the campaign better than those who had myocardial disease. An infantry captain and two lieutenants who had well-compensated mitral disease were able with the aid of digitalin to endure the fatigue of the life of combat. An officer, aged 23 years, who had retired from the army in consequence of aortic insufficiency, rejoined and took part in the battle of the Marne, but forgetting to take his digitalis his heart dilated. He rested for a fortnight and then returned, but was discharged in spite of his protestations. An officer, aged 26 years, who had retired from the service in consequence of aortic insufficiency, re-engaged as an aviator. In the middle of August he fell with his machine from a height of 20 metres. His shoulder was dislocated and he was covered with bruises. He came to M. FIESSINGER for examination of his heart. He was doing well, and he soon resumed aerial work. A major in the medical corps suffering from mitral obstruction remained alone on the field with more than 700 wounded after the disaster in Lorraine to the 15th Corps. He was taken prisoner and afterwards exchanged for a German army surgeon taken prisoner by the French. He rejoined his corps and passed many days and nights at the front until increasing dyspnoea vanquished him. To M. FIESSINGER'S advice to take a fortnight's rest he replied that it was impossible. He kept his bed for 48 hours and then rejoined. Two officers—one an "intendant-général" in the Army Service Corps, on whom depended the supplies of food of 350,000, the other a major in the veterinary service, who slept on straw for several weeks at a time, treating men more often than horses, and giving numerous injections of

antitetanic serum—suffered from renal heart with tachycardia and cardiac gallop. Yet they have been through the campaign for over three months and are still well. Such devotion, said M. FIESSINGER, is a magnificent page in the annals of France.

We have every sympathy with the urgent desire of him who, despite some physical condition that might prove a bar, desires to enlist, but a good physical standard of all is an absolute necessity for the common safety of an army. Modern conditions of war have made that standard much more elastic; place has been found in the ranks for the small man, for the man who is too tall (theoretically) for his weight, for the man who wears glasses, and for much other first-class material that formerly could not be employed; but there should be no leniency shown towards the applications of those whose infirmities might prove a source of danger to others. The recruit who deliberately conceals his epileptic history is not serving his country really; he cannot remain in the ranks while subject to such a disease, and his detection may be the sequel to a tragedy. It is possible to condone the case of the healthy middle-aged man who confuses his chest measurement with his age in entering himself as 37; many victims of cardiac disease do not themselves know their plight, and if they are admitted to the army the fault is not theirs; but those who conceal conditions difficult to diagnose, which, if known, would rightly debar them from military service, make an error—even though a gallant one; for they might break down at a moment when upon their efficiency depended the safety of many comrades.

The Physiology of the Minute Quantity.

A GOOD many years ago chemists talked of catalytic action, and the expression then was, as most must confess, merely a convenient expression. What it really meant was that a chemical reaction between two agents was highly stimulated by a third, albeit this third body was infinitesimal in quantity and unchanged. We now possess a quite large number of examples in which catalysis plays an important and even essential part not only in inorganic chemical changes but in life processes also. Taking an example of pure chemistry first, the union of hydrogen and oxygen in practically unlimited quantity may be effected, as is well known, by mere traces of colloidal platinum, while without its intervention the elements might remain for ever apart. The common and striking feature of catalysis is that the quantity of the catalyst is very small compared with the quantities of the main reacting substances, and this feature is also illustrated in the action of the organic catalyst, the enzyme. The enzymes, in fact, bear a close analogy to the ordinary inorganic catalysts. Thus the enzyme invertase is capable of inverting 100,000 times its own weight of cane

sugar, and its activity is practically unimpaired through the process, particularly when the ultimate product is removed as fast as it appears.

A more recent development of catalysis has been made in plant physiology, which promises to be of the utmost importance to agriculture, while the circumstances in which we live necessarily turn the attention of thoughtful people to the productivity of the soil. It has been found that minute traces of certain mineral bodies may promote or hinder healthy plant growth, just as the presence of a minute quantity of iodine in the thyroid gland determines its activity. In a suggestive monograph forming one of the agricultural series issued from the Cambridge University Press,¹ Dr. WINIFRED BRENCHLEY records the results of some experiments made at Rothamsted experimental station on the influence of certain metallic compounds on vegetable growth. The trials are by no means complete, but they indicate that a very interesting and entirely unexplored field is being approached. The prospect at any rate is opened up of the possibility of utilising certain stimulating compounds as artificial manures, and Dr. BRENCHLEY points out that as only small traces are beneficial, larger amounts being poisonous to the plant, it is obvious that only small quantities would be needed. Again, the compounds are not usually very expensive and thus a considerable increase of crop for a relatively small outlay might be anticipated if no complicating factors intervened. In this interesting investigation a very limited number of plant poisons were investigated, but sufficient evidence was adduced to show that even these few differ considerably in their action upon plant life. While, to quote some examples, certain compounds of copper, zinc, and arsenic are exceedingly poisonous, compounds of manganese and boron are far less deleterious, so that a plant can withstand the presence of far more of the latter substances than of the former. The tested compounds of copper, zinc, and arsenic do not seem to stimulate growth, even when they are applied in the smallest quantities, whereas very dilute solutions of manganese and boron compounds decidedly increase growth. A differentiation, however, is shown even in this stimulative action, for while manganese is the more effective in stimulating barley, boric acid is far more potent for peas, the shoots being particularly improved. The minute quantity of manganese sufficient to produce stimulation is very remarkable, since 1 part of the sulphate in 100 millions was found to exercise a beneficial action. The yields were increased in some experiments by as much as 41 per cent. in the case of spinach, 19·4 per cent. in the case of peas, 13·9 per cent. in the case of flax, and 5·3 per cent. in the case of barley. In some investigations carried out with rice in Japan the harvest of grains was increased by one-third owing to careful manganese

¹ Inorganic Plant Poisons and Stimulants. By Winifred h. Brenchley, D.Sc., F.L.S. Cambridge University Press.

stimulation. This stimulation is assumed to be due by some observers to an increase in the oxidising powers of the oxidising enzymes, so that destruction of the hindering compounds can be accomplished as quickly as they are formed, growth thus continuing more rapidly. Manganese possibly intervenes as a catalytic agent in the material changes of which plants are the seat, and the metal thus participates in an indirect manner in the building up of the tissues and in the production of organic matter. And this great accelerated synthetic result is the outcome of an application of a solution containing 1 part of the salt in 100 million parts.

In considering the experimental work that has so far been done on the subject of poisoning and stimulation Dr. BRENCHELY concludes that it is not true to maintain the hypothesis which some have done that all inorganic plant poisons act as stimulants when they are present in very small quantities, for while some poisons do increase plant growth under such conditions others fail to do so in any circumstances. It is more probable that some inorganic poisons act as stimulants when present in small amounts, the stimulating concentrations varying both with the poisons used and the plants on which they act. The researches on this subject have attracted considerable attention, and their development will be watched with the keenest interest. The particular work on agricultural applications apart, it is obvious that as these investigations are pursued they may help to clear up much of the obscurity which surrounds the remarkable action of small entities in the human body.

Annotations.

"Ne quid nimis."

FAMILY RESEMBLANCES.

HAD the "Slingsby Case" been tried in less stirring times it certainly would have attracted a greater share of public attention, particularly from those who are interested in the inheritance of physical characters. Mr. Justice Bagnall Deane recognised a close degree of resemblance between the boy defendant and his father, Mr. Charles Slingsby, particularly in the case of the lower jaw; Sir George Frampton detected a likeness between the ears of the boy and his mother. On the day on which the learned judge gave his judgment a well-known anthropologist, an anatomist famous for his accuracy, descended in a lift with two men and a boy, all three of whom stared stolidly at the advertisements on the wall. One of the men was short and dark, the other fair and of medium height. The expert at once assigned the little boy as son to the fair man from their close resemblance. As the lift gates swung open the boy took the dark man by the hand, called him "dad," while the fair man went his own separate way. In telling us his experience he adds: "Another case of mis-identification came under my notice on the evening of the same day. An intelligent and experienced lady called on a friend

who took her up to the nursery to see the latest born. The visitor found two nurses and two babies, and exclaimed, 'Well, I need not ask which it is; this one is your image.' She then selected the wrong child." From such cases one must conclude that general resemblances may prove misleading. But it is otherwise with particular features, such as the Hapsburg lip. Medical men are well aware of such features; a nose, an eye, or an ear may have such a pronounced shape that a family identification may be made with certainty. Individuals with pronounced features are in the minority. There is no question that such features may be and are inherited. In many instances the characteristic form is not apparent in the young; it becomes fully developed after adolescence, and this is especially true in the case of the nose, and is also the case with the lower jaw. The boy defendant is 4 years of age; in the next 16 years his jaw will be remodelled over and over again to make room for the permanent molar teeth, the teeth which will replace his milk set, and to fit the growth of the upper jaw; it would be at maturity we should expect a real, not an apparent, resemblance of the paternal form of jaw to appear. The ear offers a more certain means of identification of likeness, but very few men have studied this complex structure so closely as to be in a position to offer an expert opinion as to degree of likeness. In the photographs which have been published of the parties in the Slingsby case an expert has little difficulty in recognising what was apparently regarded as a striking feature of the "Slingsby" ear. The resemblance lies in the degree to which the hinder border of the ear is folded over so as to form a welt. It is well known that the folding of the ear margin is a result of retrogression; the more the border is folded over the greater is the degree of developmental retrogression. There is no folding of the border of the ear in the more primitive apes; in some of the higher apes, especially in the orang, there is a high degree of infolding, for the ear of the orang is more retrograde than that of most human races. A considerable degree of infolding of the ear is so common that an anthropologist would give it only a slight value in working out resemblances. Sir George Frampton's method of observation we do not know, but we must admit that sculptors have certainly a right to express an opinion. It was Thomas Woolner who drew Darwin's attention to the presence of a nodule on the welt of the human ear which the great evolutionist recognised as a remnant of the ancient pointed tip. That all parties concerned in the Slingsby case should show a trace of the ancient tip is not a matter for surprise; the ear is exceptional which shows no sign of this ancient mark.

MEDICAL RECIPROCITY WITH BELGIUM.

THE Executive Committee of the General Medical Council at its last meeting on Jan. 22nd had before it the recent Order in Council extending Part II. of the Medical Act of 1886 to the kingdom of Belgium.¹ The committee considered evidence submitted to it by Belgian professors, graduates, and others with regard to the course of study and examinations which candidates had to undergo in order to obtain the degree of Doctor of Medicine in the universities of Belgium and the legal authorisation

¹ THE LANCET, Jan. 16th, 1915, p. 143.

to practise in that country. The committee was satisfied with the evidence produced, and resolved as follows:—

That so long as the Order in Council of Jan. 7th, 1915, remains in force any person who produces evidence satisfactory to the Registrar that he has obtained the degree of Doctor of Medicine in the Belgian universities of Brussels, Ghent, Liège, and Louvain, and is legally authorised to practise medicine, surgery, and midwifery in Belgium; and who satisfies the Registrar as to the other particulars specified in Section 12 of Part II. of the Medical Act, 1886, shall be entitled to be registered in the Foreign List of the Medical Register.

Further communications received by the Registrar of the General Medical Council, through the clerk of the Privy Council and His Majesty's Minister at Havre, from the Belgian Government, afford official confirmation of the evidence placed before the Executive Committee as to the education and examinations on which medical qualifications are conferred by Belgian universities and colleges. The Acting Minister of the Interior, in the course of his note to Sir Francis Villiers, used the following appreciative words: "Veuillez croire, Excellence, que le Gouvernement Belge est très sensible à cette nouvelle marque de la sympathie de l'Angleterre et qu'il en remercie vivement les autorités de votre pays." In the absence of complete information on Jan. 22nd, the question of the recognition of Belgian dental diplomas was held over until the next meeting of the Executive Committee.

THE HUMAN STOMACH AND THE CANALIS GASTRICUS.

It has been commonly supposed that fluids and solids on being swallowed must necessarily be mixed up in the stomach, but there is now much important evidence to show that such a view must be revised. It is held that fluids can be swallowed, in fact usually are swallowed, and yet not mix with other ingesta within the lumen of the stomach; they pass on, by the aid of a special arrangement to be immediately noted, direct from the cardiac orifice to the pylorus. Comparative anatomy has shown that such an arrangement holds good for ruminants, and at a later time it was discovered that carnivora possess the same faculty, despite the fact that in them the stomach is a single chamber. Recently Dr. F. T. Lewis has called attention to a canal along the lesser curvature of the human foetal stomach; he has called it the "canalis gastricus." He says "it suggests a continuation of the oesophagus and may become a tube during its physiological activity, by the approximation of its lips." Some recent radiographic and anatomical researches by Dr. Geoffrey Jefferson in the *Journal of Anatomy and Physiology* (1915, vol. xlix., p. 165) give further strong support to the likelihood of some action such as this persisting in adults and realising in this way a selective course to the pylorus for fluids. Screen examinations of 22 normal people after being given a mixture of bismuth oxychloride and milk of the consistency of thin cream showed that in 18 instances the fluid was confined to the lesser curvature; in the other 4 cases it spread rapidly over the sides of the stomach, but these stomachs were atonic. That such a course does not merely represent the shortest path gravity would demand is shown by the holding up of some portion just below the cardiac orifice. Nor does Dr. Jefferson agree wholly with Dr. Hertz that the normal empty stomach is contracted down like a piece of small intestine, the localised

stream being accounted for in this way. That the stomach really makes a coördinated effort to direct the fluid into a channel at its lesser curvature is thus suggested by X rays. Finally, there must be recognised the active part played by the oblique muscle of the stomach in accomplishing this local canalisation. It is probably by the contraction of its upper fibres that the bismuth, as seen by the screen, was so constantly held up below the cardiac orifice. This sheath of muscle, in fact, is of more importance than was supposed, and its action aids in forming this functional "canalis gastricus." Further proof of the specialisation of the lesser curvature of the pars cardiaca for some function other than that of slowly pressing the food out into the outer pyloric part is shown by the marked difference in the action of the muscle along the lesser curvature as seen by X rays, the change occurring at the incisura angularis. The whole diameter of the pars pylorica takes part in active peristaltic waves coursing towards the pylorus. It is, however, very rare to see any indentation of the lesser curvature in the pars cardiaca. There thus seems to be a fundamental functional difference between the two parts, which gains its best explanation from the facts above discussed.

SMALL-POX, VARICELLA, AND "ALASTRIM."

THE discussion at the Royal Society of Medicine¹ arising out of a paper read by Dr. W. G. Armstrong on the subject of the epidemic of small-pox at Sydney in 1913 was in many respects interesting and suggestive. The peculiar feature of the epidemic in question was the mildness of the symptoms, although the population affected was largely unvaccinated. Thus, in many instances there were but few cutaneous lesions, while in a patient who presented a severe confluent eruption on the face and extremities the constitutional disturbance was so slight that the man's complaint was only of the insufficient food given him and of the soreness of his feet if he tried to stand on them. There was only one death among over 1000 cases of the disease. Coincidentally with this epidemic of small-pox there was an increase in the prevalence of varicella, but the behaviour of the two diseases with regard to vaccination negated any possibility of the epidemic being of hybrid character. Epidemics of specially mild small-pox have been observed in many parts of the world and have received different names, such as milk-pox, Cuban itch, Spanish measles, and "alastrim"; and doubt has prevailed as to the identity of these mild forms with true variola. Dr. C. J. Martin quoted a report by Ribas, of São Paulo, who upheld the diversity of the local disease known in Brazil as "alastrim" from small-pox owing to its low mortality, its trivial degree of constitutional disturbance, the absence of the characteristic smell, and the possibility of successfully vaccinating patients within a short period after the attack. On the whole, the evidence is in favour of regarding all these conditions as mild variola, and the success of Dr. J. Burton Cleland and Dr. E. W. Ferguson in inoculating calves with material derived from patients in the Sydney epidemic affords powerful support to this view. Dr. Martin, however, suggests that the three diseases—small-pox, chicken-pox, and "alastrim"—are of common parentage but have become so far differentiated as to breed true at the present time.

¹ Proceedings of the Royal Society of Medicine, December, 1914, Section of Epidemiology.

REMUNERATION ON THE PANELS.

It is fairly evident that if there had been no war there would have been a considerable amount of disappointment and resentment felt by medical men on the panels of many districts owing to their receiving as their remuneration for 1914 less than they had reason to expect, and owing to their only receiving the balances acknowledged to be due by the committees after appreciable delay. In the present circumstances the war is responsible for an increase in the difficulty of the position owing to the number of insured persons who have enlisted. There are no contributions made by them or on their behalf by their employers, and owing to the drain upon clerical staffs everywhere arrears of work have accumulated, with general dislocation of business. It is too early to say what may be done in the future in order to relieve the situation, but it seems very doubtful whether committees can be compelled to find money and make payments where the ordinary working of the Insurance Act does not provide it. At the same time the hardship to the medical profession and to the druggists must be great when payments which they have had every right to expect are postponed or withheld. The medical practitioners have had to arrange the organisation of their professional work to meet the demands of their insured patients upon their time and attention, and the druggists have had to meet anticipated requirements by laying in stocks of drugs which have to be paid for. Both have to contemplate the return of many insured persons serving in the army with wounds or with impaired health, and a general alteration of the probabilities with regard to their need for medical care. For the rectification of some part at any rate of legitimate causes of complaint it may be necessary to wait until the war is over and legislation can proceed upon more normal lines than now. At present it may be urged on behalf of the medical men affected that they are entitled to demand payment upon all patients on their lists until they have been notified as provided for by Regulation 29, and that if the financial provisions of the Insurance Act do not meet the needs created by war, legislation should supply the deficit.

THE ADMINISTRATION OF THE PHARMACY ACTS.

THE annual report of the Registrar of the Pharmaceutical Society, which was presented to the council at the February meeting, shows that as regards membership the steady progress which has been revealed by these reports during the last ten years or more is well maintained. The number of members is now well over 8000, which is about half the number of registered persons; the majority of the non-members no doubt consist of qualified chemists who are not yet in business on their own account. There is also an increase in the number of names on the Pharmaceutical Register, and although this increase is only slight it is satisfactory to know there is an increase, while the fact that there has been a considerable accession to the ranks of the registered students is very promising. From the general point of view the most interesting part of the report is that which deals with the administration of the penal clauses of the Pharmacy Acts. The number of cases of alleged infringement that require investigation is still large, but smaller

than it was during the previous year. During 1914 1113 cases were investigated, and in 239 cases proceedings were instituted, and the council was successful in all but one or two. The list of offenders is headed by unqualified drug store proprietors, of whom 93 were proceeded against, the offence generally being that of keeping open shop for the sale of poisons. Among the persons by whom penalties were paid there were also a number of qualified pharmacists who had committed one or other of the irregularities which are offences under the law regulating the sale of poisons. The list of offenders also includes unqualified assistants in drug stores, unqualified managers and assistants to chemists, executors to chemists, limited companies trading as chemists and druggists, unqualified directors of limited companies, grocers, herbalists, general storekeepers, and one ironmonger, one seedsman, one oilman, one manure agent, and one unqualified assistant to a doctor. It is evident from the variety of the occupations of the persons proceeded against that the task of preventing the irregular sale of poisons is no light one. In five cases of alleged infringement of the Pharmacy Acts which had been reported it was found upon analysis that the poison asked for had been omitted from the articles purchased, and proceedings could not, therefore, be taken under these Acts; but pursuing the policy decided upon some years ago the council proceeded in two of these cases under the Merchandise Marks Acts, and the defendants were convicted for selling goods to which a false trade description was applied.

THE STREPTOCOCCUS VIRIDANS IN INFECTIONS OF THE UPPER RESPIRATORY TRACT.

AN interesting paper is published in the *Archives of Internal Medicine* for Jan. 15th by Dr. Russell L. Cecil, of New York. He adopts the classification of streptococci put forward by Schottmueller, based on the appearances of the colonies on blood-agar—namely, *S. hæmolyticus* (longus, pyogenes), *S. viridans* (mitior), and *S. mucosus*. Dr. Cecil states it to have been found by many investigators that clinically the *S. hæmolyticus* produces suppurative or phlegmonous inflammations, while the *S. viridans* usually leads to catarrhal processes. His own work has been specially devoted to determining the part played by the latter organism in infections of the upper respiratory tract. From the study of 89 cases of such infections he found the *S. viridans* to be the predominant organism in 50 cases, or 56.2 per cent. In general these infections were characterised by a mild course and a tendency to chronicity with frequent recurrences, which he attributes to the short duration of the acquired immunity. These infections of the upper respiratory tract due to *S. viridans*, especially those of the tonsils, sinuses, and the tooth sockets, are frequently associated with endocarditis and arthritis, and he is of opinion that there is a good deal of evidence that the latter conditions are secondary to the former. He has found autogenous vaccines to be of considerable value in cases where the structural changes are not too advanced, but he takes care to point out that in cases of bronchitis with emphysema or bronchiectasis, old sinus infections with thickened walls, and advanced pyorrhœa with retraction of the gums, vaccines can bestow only limited benefits. He believes that vaccines are more especially

valuable in the prevention of recurrences, and suggests that prophylactic vaccination against infections of the upper respiratory tract deserves more attention. He states that his own experience indicates that most persons who suffer from frequent colds are susceptible to one particular organism with which they are constantly being reinfected. Dr. Cecil's paper is an interesting and practical contribution to a subject of general interest.

ON Wednesday next, Feb. 17th, at 5 P.M., before the Historical Section of the Royal Society of Medicine, Sir Alexander Simpson, of Edinburgh, will read a paper on Jean Astruc (1684-1766), of the Montpellier School, the historian of syphilis, but nowadays more famous in theological circles as the founder of the higher biblical criticism. This is the aspect which will be specially considered, we understand, by Sir Alexander Simpson.

THE Morison lectures will be delivered before the Royal College of Physicians of Edinburgh by Dr. W. H. B. Stoddart within the hall of the College, 9, Queen-street, Edinburgh, on Monday, Wednesday, and Friday, March 8th, 10th, and 12th, commencing each day at 5 o'clock P.M. The subject of the lectures will be the New Psychiatry.

THE annual meeting of the British Medical Association, which was to have been held at Cambridge this summer, will not take place. The statutory annual general meeting of the Association and the annual meeting of Representatives will, however, be held.

MEDICINE AND THE LAW.

Medical Certificates and the Education Authorities.

At the Bangor police court recently a summons taken out by the education authority against Ernest Kenrick, the father of a boy who had been kept back from school on the ground of ill-health, was dismissed by the bench after hearing the evidence of Mr. Helsby, the boy's medical attendant. Mr. Helsby stated that in his opinion the boy was too delicate to attend school, and he had advised that he should be kept at home during the winter. He had given no certificate because he did not think that the education authority could compel parents to obtain and pay for medical certificates in such circumstances, and he knew that the authority did not pay for them. In other districts where the education authority paid for certificates he had given them. He was always willing to give the required information to school attendance officers. The clerk to the magistrates advised the bench that it was doubtful whether the education authority had any right to put parents to the expense of obtaining medical certificates, especially as the attendance officers could always call upon the medical men. He advised the magistrates that they had no option but to dismiss the case. Mr. Helsby explained that he might spend a great deal of time in writing certificates which the majority of parents could not afford to pay for, and that he attended the court in order to maintain his position on the question of principle. He is to be congratulated upon having done so with complete success, and it is to be noted that

his conduct in the matter was not only legally correct but reasonable and conciliatory, as he was willing to give verbal information to the attendance officer. Presumably that official would not find it necessary to call upon the medical man in all cases where illness was alleged as a ground for failure on the part of a pupil to attend school, but would satisfy himself as to the fact of illness by a visit to the child's home. Otherwise the tax of personal answer to inquiries would fall as heavily upon the medical man as that of signing certificates without remuneration. It would be fairer and more businesslike if all education authorities adopted a uniform practice of requiring and paying for certificates in cases where any uncertainty indicates that they are desirable.

Prescription by Telephone.

At an inquest at Burton-on-Trent lately it was proved that death had been caused by the error of a dispenser to whom the medical man attending the deceased had telephoned, instructing him to send a solution of a certain drug containing 1/75th of a grain for hypodermic injection. In taking down the message the dispenser mistook 1/75 for 0.75, and adopted the latter figure in preparing the solution, with the result recorded. The mistake should be noted, as all of us who use the telephone are familiar with the mistakes made in telephoning with regard to figures, even when the listener is a practised operator.

A Pernicious Quack Sentenced.

Arthur Denison Light, described as principal of the British Health Institute and publisher of a periodical called "Power, Purity, and Progress," was sentenced to three months' imprisonment at the Old Bailey recently upon a charge of attempting to obtain money by false pretences. Light, against whom *Truth* had frequently warned the public, pretended to treat diseases of the sexual organs and sold books and appliances of the character usual with such gentry. One of Light's ingenious devices was to offer to make examinations of urine free of charge. He was met here by the ingenuity of a detective, Inspector Wagstaff, who submitted an example consisting of cold tea and soap, and was informed that the patient supposed to have passed it was suffering from catarrh of the bladder. Inspector Wagstaff and a Mr. Leader, a member of a young men's association called the "Alliance of Honour," who got into communication with the prisoner and placed the correspondence in the hands of the police, are to be congratulated upon having secured for him a sentence which, if inadequate, will serve as a warning to him and others.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next meeting of this association will be held at 11, Chandos-street, Cavendish-square, London, W., at 3.15 P.M., on Thursday next, Feb. 18th, under the presidency of Dr. David G. Thomson. A paper will be read on Meningo-Vascular Syphilis by Dr. Roy M. Stewart, with lantern demonstration. There will be no quarterly dinner.

LITERARY INTELLIGENCE.—Messrs. Smith, Elder, and Co. announce for publication, under the title of "The Minor Horrors of War," a number of articles which have appeared since the beginning of the war in the *British Medical Journal* by Professor A. E. Shipley, the Master of Christ's College, Cambridge. These articles deal with various insect and other pests which cause disgust, discomfort, and often disease amongst our troops now fighting in all quarters of the globe.

A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

COMMITTEE FOR THE INVESTIGATION OF ATMOSPHERIC POLLUTION:

Summary of Reports for Month ending Nov. 30th, 1914.

1	2	3	4	5	6	7	8	9	10	11	12

Duncan, F.I.C., Malvern; E. Knecht, Ph.D., M.Sc., Cheadle Davyhulme, Fallowfield, School of Technology, University, Whitefield (Manchester collections); J. J. Dunn, D.Sc., Newcastle-on-Tyne; Professor W. P. Wynne, Attercliffe Burial Ground, Hillsborough Park, Meersbrook Park, Weston Park (Sheffield collections); S. H. Davies, M.Sc., York; J. W. Biggart, F.I.C., Greenock; A. Scott Dodd, B.Sc., F.I.C., and R. M. Clark, B.Sc., Leith and Paisley respectively; Messrs. R. R. Tatlock and Thomson, Coatbridge. The correspondents referred to in col. 2 are for the most part public health authorities.

THE CORNWALL COUNTY ANALYST AND PRESERVATIVES IN FOOD.—At the last meeting of the General Purposes Committee of the Cornwall County Council the county analyst (Dr. Kitts) reported that during the past four years slightly over 1 per cent. of the milks had been treated with a preservative and 5 per cent. of the butter samples. In margarine 95 per cent. of the specimens examined had contained a boric compound in small quantities. Dr. Kitts stated that when preservatives had been used in other articles of diet the user had sometimes not even known the name of the powder he had used, to say nothing of its possible physiological effects; the vendors persuaded the users that the substances were perfectly harmless. Dr. Kitts added that it was outrageous that the public should be constantly dosed with "medicinal substances" by persons having no knowledge of their proper use or effects upon the human system.

BRISTOL INSURANCE COMMITTEE.—At the last meeting of this committee it was reported that the total number of persons on the "doctors' lists" was now 106,704, an increase of 7000 upon the previous year. The number of prescriptions dispensed during 1914 was 382,000, a rate of over 1000 a day.

SCARLET FEVER IN BELFAST.—The attempt to limit the spread of scarlet fever in Belfast by closing the public schools last Christmas has not succeeded. During the week ended Jan. 16th there were 41 notifications of the disease, as compared with 37 in the previous week, while in the week ended Jan. 23rd 55 cases were notified. Indeed, there seems to be a recrudescence of the epidemic, which has now prevailed so many years in Belfast. In the progress of preventive medicine the inability to restrict scarlet fever is the most striking exception.

MEDICAL PRACTICE ON THE EAST COAST: THE POSITION AT GREAT YARMOUTH.

(BY OUR SPECIAL COMMISSIONER.)

Great Yarmouth, Feb. 8th.

To counterbalance the inevitable economical pressure felt by a nation at war we have generally some communities more thriving than others, because they can provide some of the varied material—ships, guns, weapons, clothes—needed for the prosecution of hostilities; other localities receiving no such set-off will necessarily suffer as more and more money is consumed. Prominent among the English towns which have to bear the burden of war time stands Great Yarmouth, which has been attacked directly and twice by the enemy, and suffers indirectly by the collapse of its main sources of income. Fortunately, the first attack, a bombardment, did no harm. Presumably the German ships mistook the distance, for all their shells fell short of the town. This first attack occurred, it will be remembered, at the beginning of November, and its memory was fading away when on the night of Jan. 19th airships hovered over the town dropping bombs—this time with fatal effect in that several lives were lost, but no great destruction of buildings occurred. Financially speaking, rumour did vastly more harm to Yarmouth than the German bombs.

The netting of fish and the letting of lodgings are the principal sources of income at Yarmouth, and the war has dealt hardly with both. A considerable proportion of the inhabitants rent houses with the intention to secure lodgers for a part of them, and render themselves liable to pay rent and rates far and away above what they would pay in either direction for their personal use. Of course, they count on making up the difference advantageously by letting rooms or by taking in boarders. The season at Yarmouth is very short; it reaches its climax in September and was commencing at the end of July. War was declared on Tuesday, August 4th. Of the visitors who were already at Yarmouth hardly any remained beyond the end of that week and none came to take their place the following week. Gradually braver spirits returned, but the town never recovered its holiday population as some more fortunate watering places further south appear to have done. Perhaps, if there had been fewer sinister rumours floating about, the season might not have been so completely spoilt, but every parent who looked at an atlas recognised that if attack was possible Yarmouth was a very vulnerable spot, and decided not to venture there with children. Mere digging of trenches would not have frightened the public away from Yarmouth any more than it did from Broadstairs. But being nearly opposite the German naval base, it was but too correct to conclude that Yarmouth would be attacked, if attack became feasible, while experts were aware of the possibility of a dash from fast enemy cruisers. Therefore, those who, in spite of the war, were not disposed to forego their seaside holiday selected some place that seemed less exposed than Yarmouth.

The Effect on the Local Industries.

The next source of income in Yarmouth is the fishing industry, especially the herring trade. This gives employment to a large number of fishermen, and also to regiments of Scotch women, who follow the fishing smacks along the coast to clean and pack the herrings. They arrive just after the sea-bathing season concludes, and in the South Side near the fish-docks fill the lodgings abandoned by the holiday folks. But as most of the herrings are packed in barrels, preserved in brine, and exported to the North Sea and Baltic ports this trade is paralysed by the war. It so happens that the herring women have found during the collapse of their trade a valuable method of earning money. Exposed to all weathers, they know how to knit themselves warm woollen underclothing. To-day they can find employment knitting clothes for the soldiers at the front; but they do this at home in Scotland, not at Yarmouth. The poorer lodging-house keepers, those, for instance, who used to receive the women employed in fish-cleaning, are doing very well in billeting soldiers. On their side the soldiers are more comfortable than usual; for being housed by lodging-house keepers the cooking and attendance generally are better than in private families which do not make a business of receiving strangers.

The Prosperous Inhabitants Suffer Most.

The lodging-house keepers, however, who are able to balance the loss of their ordinary business by attending to soldiers do not belong to the class which best pays its medical attendants. The central and richer part of the town suffers most, and its inhabitants are not likely to ask for help. Employees of different sorts in commercial spheres provided modest payments for board and lodging during the winter months on condition that they retired to small rooms during the summer holiday rush. Last year there was no summer rush, and many of these winter clients have enlisted. The health authorities, I found, do not think there is as much poverty as usual among the labouring class and those sections of the community who in normal times suffer most. But other sections who, as a rule, do not suffer at all are badly hit, and they are the best ratepayers and the medical practitioners' principal source of income. The municipal authorities are greatly concerned, for they do not like to prosecute good citizens. The medical practitioner feels the same compunction about pressing for his fees. Thus one medical practitioner told me that a patient could not pay what she owed him because her lodger owed her £18, and the lodger could not pay because his occupation had practically ceased at the outbreak of war. Then those connected with the law have little or nothing to do. No one is going to institute legal proceedings while the war lasts. Jewellers, tailors, dressmakers all suffer. The war is a good reason for wearing out all the old clothes. Persons who have private means cannot realise their investments, and those who have placed money in German or Austrian enterprises may never see any of it again. Tradespeople who deal in objects that are not absolutely necessary do very little trade, and it will be seen that these are just the very classes among whom medical practitioners find their best paying patients. Even those who have money feel unsafe and think it more prudent to economise. Therefore, they only send for their doctor when it is absolutely necessary. Or, worse still, they profit by the fact that they have the means to leave the town altogether, though this is not the general rule.

The personal economy and the cessation of trade in certain directions could of course be paralleled all over the country, but in Yarmouth the depression is accentuated by the collapse of the two great industries.

Vast Gratuitous Medical Attendance.

The poorer sections of the community are, if anything, better off than before the war. The labourers readily find employment, while many of them have enlisted, and there is a good deal to do for those who remain. But the abolition of the militia by the establishment of the Special Reserve has been a great loss to the town of Yarmouth. The Norfolk Militia was almost a crack regiment. His late Majesty, Edward VII., was their colonel, and he used to come down to Yarmouth to review them, thus bringing much money to the town. Many of the old militiamen accepted a small fee to become reservists. From the town of Yarmouth alone, out of its 57,000 inhabitants, no less than 500 were called to the flag as reservists. A large proportion, not only of these reservists but of those who enlisted since the beginning of the war, were insured persons, but their wives and children were paying patients. Now this important source of income is lost to the profession, for the wives and children of those with the Flag are being attended in the main gratuitously.

The Dependents of the Soldiers.

Yielding to a generous and patriotic impulse, practically all the practitioners at Yarmouth agreed to attend gratuitously the dependents of those who enlisted. The chemists, on their side, offered not to charge for the work of dispensing the drugs, and the Prince of Wales's Relief Fund was looked to to reimburse the bare cost of the drugs consumed. But quite a large proportion of these dependents are better off than they were before the outbreak of war. The allowance they get from the War Office is in many cases higher than what their husbands could afford to give before they enlisted, and yet in those days they had to pay for medical attendance. Now the dependents can claim the services not only of the panel but of the non-panel doctors, and neither chemist nor doctor receives any remuneration. The Yarmouth practitioners are beginning to wonder why dependents who are, generally speaking, better off than they were formerly

should come upon them for gratuitous advice. This is all the harder to bear as so many patients who used to give reasonable fees are now so impoverished that they really cannot pay anything. There is as much, indeed more work to be done, but much less to receive than formerly. Thus I called on a non-panel doctor who I found had been kept from his dinner by nine army dependents. After giving them gratuitous advice a tenth visitor came, but instead of a paying patient he proved to be the water-rate collector.

After-effects of the Air Bombs.

It may not, perhaps, be generally realised that the airship bombs have materially increased the amount of work falling upon the medical practitioners. It is not the casualties that count: two killed, three wounded, and minor injuries make but little difference in the total number of patients ill from all causes. But there has been a great amount of illness and some deaths among those who were not struck. People with weak hearts, startled by the noise and alarm, had violent attacks of palpitation, and several of the deaths a few days after the bombardment were due to the shock. Then there are the highly nervous or neurotic persons. One case was that of a woman who could not be induced to sit still but was constantly springing to her feet, pacing up and down the room, wondering what she would do if Zeppelins dropped more bombs. In another patient the pulse, previously normal, continued beating at 105 per minute a fortnight after the explosions. These certainly did make a very great noise, and being absolutely unexpected were all the more startling. Now that the people are a little more accustomed to such aggression, it is probable that another attack would occasion much less disturbance. Nevertheless, the emotion they cause must seriously affect persons with weak hearts or highly nervous temperaments.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

The undermentioned has been granted a temporary commission as Surgeon in His Majesty's Fleet: Arthur Ernest Iles.

The following appointments have been notified:—Staff-Surgeon: B. R. Bickford to the *Pembroke*, additional. Temporary Surgeons: G. M. Oakden to the *Prince George*; D. R. Bedell-Sivright and G. S. Aspinall to the *Victory*, additional, for Haslar Hospital; W. B. Cunningham and W. L. Glegg to the *Pembroke*, additional, for Chatham Hospital, all as additional medical officers; A. G. Stewart and D. S. MacKnight to the *Vivid*, additional, for disposal.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon: W. H. Bleadon to the *Pembroke*, additional.

ARMY MEDICAL SERVICE.

Colonel John C. Culling is retained on the Active List under the provisions of Article 120, Royal Warrant for Pay and Promotion, 1913, and to be supernumerary (dated Feb. 7th).

ROYAL ARMY MEDICAL CORPS.

Brevet-Colonel Frederick Smith, D.S.O., is retained on the Active List under Article 120, Royal Warrant for Pay and Promotion, and to be Supernumerary (dated Feb. 8th).

The undermentioned are granted temporary rank as follows:—To be Lieutenant-Colonel: Dated Jan. 19th: Robert Thomson Leiper. To be Lieutenants: Dated Jan. 19th: Reginald Percy Cockin and John Gordon Thomson.

The undermentioned relinquish their temporary commissions with the Allied Forces Base Hospital:—Dated Feb. 1st: Major Arthur G. Whitehorne-Cole, Major Barnard Hudson, Major Philip M. Heath, Captain Ernest D. Roberts, Lieutenant Oswald T. Dinnick, and Lieutenant William M. S. Robinson.

Sydney George Leyland Catchlove to be temporary Captain (dated Jan. 11th).

Lieutenant Gwilym L. Pierce relinquishes his temporary commission (dated Jan. 23rd).

Temporary Lieutenant James G. Ferguson resigns his commission (dated Feb. 4th).

The undermentioned to be temporary Lieutenants:—Dated Jan. 16th: Dominic Francis Curran, John Hastings Glover, William Pritchard-Airey, and James Morrison. Dated Jan. 18th: Herbert William Fankhausen, James Churchill Dunn, Wilfred Conrad Stanley Wood, Donald Watson, Fergus Hay Young, George Allan Maling, Stanislaus Reader, Walter Netherwood Rishworth, Leonard Andersen Pearce Hurt, and Samuel Ridley Mackenzie. Dated Jan. 20th: Charles Patrick Valentine MacCormack, Archer Ryland, Charles James Glasson, James Ninian George William

McMorris, and Henry William Doll. Dated Jan. 21st: James Tate, Frank Llewellyn Gill, William Alfred Taylor, Charles Birch, Arthur William Hunter Donaldson, Henry Sydney Colchester Hooper, John Frederick Venables, Edward Benjamin Sunderland, Clive Watney Roe, Frank Cyril Greig, John Phillips Blockley, Desmond William Beamish, William Leslie, Robert Walpole Murphy, James Parker, Arthur Poole, Gerald Robinson, Cyril Carlyle Beatty, Patrick Steele, William Armour Brown, Reginald Hannay Fothergill, and Desmond Manus MacManus. Dated Jan. 22nd: William Gerald Ridgway, Robert Aikin Wright, James Hill, Bevil Molesworth Collard, Thomas Joseph Redmond Maguire, and Harold Myrie Cory.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Robert Dunlop Goldie to be Captain.

Supplementary to Regular Units or Corps: Royal Army Medical Corps.

The undermentioned Lieutenants are confirmed in their rank: John S. Dockrill, Henry P. Whitworth, Thomas H. S. Bell, Francis A. Duffield, John J. D. La Touche, Joseph H. Baird, John J. Molyneaux, John Stephenson, James Purdie, Clark Nicholson, William S. Wallace, Samuel D. G. McEntire, Gerald G. Alderson, Arthur A. Smalley, Wilfrid B. Wood, Francis A. Roddy, Harold A. Crouch, Herbert S. Milne, John S. Pooley, Quentin V. B. Wallace, William H. Nicholls, Henry Alcock, John Kennedy, and Thomas F. Kennedy.

The undermentioned to be Lieutenants (on probation): Henry Richard Sheppard, Cadet of the Officers Training Corps, and Robert Harvey Williams, ex-Cadet of the Officers Training Corps.

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd London (City of London) Field Ambulance: Captain (Honorary Lieutenant in the Army) William E. Rielly, from the Territorial Force Reserve, to be Captain.

2nd London (City of London) General Hospital: Maynard Horne to be Captain (temporary). Lieutenant Horace G. L. Haynes, from 2nd North Midland Field Ambulance, to be Lieutenant.

Sanitary Service: Alfred Ernest Williams to be Captain, whose services will be available on mobilisation.

3rd Northern General Hospital: Norton Milner to be Captain, whose services will be available on mobilisation.

1st Southern General Hospital: Robert Beatson Dennis Hird to be Captain, whose services will be available on mobilisation.

South-Eastern Mounted Brigade Field Ambulance: Captain Charles Holt Caldicott, from Attached to Units other than Medical Units, to be Captain. Captain Arthur Lewis Heiser, from Attached to Units other than Medical Units, to be Captain.

2nd Home Counties Field Ambulance: Captain James Dundas, from Sanitary Service, to be Captain. Lieutenant Ernest Mannering Morris, from Attached to Units other than Medical Units, to be Lieutenant.

1st London (City of London) Sanitary Company: Andrew Alexander McWhan to be Lieutenant.

2nd North Midland Field Ambulance: Lieutenant Hubert Pinto-Leite, from the 2nd London (City of London) Field Ambulance, to be Lieutenant.

2nd Lowland Field Ambulance: To be Lieutenants: Stephen Anderson MacPhee and Colin Cameron Philip (late Cadet, Edinburgh University Contingent, Senior Division, Officers Training Corps).

2nd Northumbrian Field Ambulance: William Smith to be Lieutenant.

Attached to Units other than Medical Units.—To be Lieutenants: William Brown and William Alfred Philipps.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last census, 8680 births and 6995 deaths were registered during the week ended Saturday, Feb. 6th. The annual rate of mortality in these towns, which had been 18.8, 18.0, and 19.2 per 1000 in the three preceding weeks, further rose in the week under notice to 20.1 per 1000 of their aggregate population, estimated at 18,134,239 persons at the middle of 1914. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 19.1, against 20.0 per 1000 in London. The annual death-rate last week ranged from 10.3 in Ilford, 10.9 in Swindon, 11.8 in Southampton, 12.5 in Edmonton and in Warrington, and 12.9 in Wakefield, to 29.9 in Great Yarmouth, 31.6 in Brighton, 32.5 in Merthyr Tydfil, 35.2 in Stockton-on-Tees, and 40.7 in Cambridge.

The 6995 deaths from all causes were 302 in excess of the number in the previous week, and included 513 which were referred to the principal epidemic diseases, against numbers increasing from 454 to 483 in the three preceding weeks. Of these 513 deaths, 210 resulted from measles, 123 from whooping-cough, 72 from diphtheria, 68 from infantile diarrhoeal diseases, 22 from scarlet fever, 17 from enteric fever, and 1 from small-pox. The mean annual death-rate from these diseases was equal to 1.5, against 1.4 per 1000, in each of the two preceding weeks. The deaths attributed to measles, which had been 195, 206, and 191 in the three preceding weeks, rose to 210 last week, and caused the highest annual death-rates of 2.5 in Plymouth, 2.7 in Grimsby, 2.8 in Wigan, 3.1 in Gateshead, 3.5 in Darlington, 3.6 in Cambridge, 4.1 in St. Helens, 4.8 in Rotherham, 6.7 in Merthyr Tydfil, and 9.7 in Stockton-on-Tees. The deaths referred to whooping-cough, which had been 76, 93, and 99 in the three preceding weeks, further rose to 123 last week; the highest recorded rates from this cause were 1.2 in Blackburn, 1.7 in Reading and in Bristol, 1.9 in Rhondda, 2.4 in Sunderland, 3.1 in Gloucester, and 3.7 in Merthyr Tydfil. The fatal cases of diphtheria, which had been 63, 83, and 77 in the three preceding weeks, further fell to 72 last week, and included 16 in London, 4 each in Southampton and Halifax, and 3 each in Tottenham, West Ham, Stoke-on-Trent, Birmingham, Manchester, Salford, and Bradford. The deaths of infants (under 2 years) attributed to diarrhoea and enteritis, which had been 75, 62, and 73 in the three preceding weeks, fell to 68 last week, of which 13 were registered in London, 7 in Liverpool, 5 in Bristol, and 4 in Manchester. The deaths referred to scarlet fever, which had been 34, 23, and 31 in the three preceding weeks, fell to 22 last week, of which 7 were recorded in London. The fatal cases of enteric fever, which had been 11, 12, and 12 in the three preceding weeks, rose to 17 last week, and included 5 in London and 2 each in Wallasey, Manchester, and Leeds. The death from small-pox was registered in London, and belonged to the borough of Fulham.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 5035 to 3647 in the ten preceding weeks, had further fallen to 3395 on Saturday last; 365 new cases were admitted during the week, against 338, 308, and 326 in the three preceding weeks. These hospitals also contained 1659 cases of diphtheria, 175 of measles, 56 of enteric fever, and 27 of whooping-cough, but not one of small-pox. The 1859 deaths from all causes in London were 101 in excess of the number in the previous week, and corresponded to an annual death-rate of 21.5 per 1000. The deaths referred to diseases of the respiratory system, which had been 472, 417, and 450 in the three preceding weeks, further rose to 497 last week, and were 150 above the number recorded in the corresponding week of last year.

Of the 6995 deaths from all causes, 216 resulted from different forms of violence and 530 were the subject of coroners' inquests, while 1864 occurred in public institutions. The causes of 61, or 0.9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Sheffield, Leeds, Bristol, Bradford, Hull, and in 51 other smaller towns. Of the 61 uncertified causes of death 15 were registered in Birmingham, 11 in Liverpool, 5 each in Manchester and Preston, and 2 each in West Bromwich, Bootle, Blackburn, and Darlington.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1224 births and 1086 deaths were registered during the week ended Saturday, Feb. 6th. The annual rate of mortality in these towns, which had been 22.8, 21.7, and 22.4 per 1000 in the three preceding weeks, further rose to 24.1 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 23.1, against 19.1 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 16.4 in Clydebank, 17.0 in Kilmarnock, and 20.8 in Edinburgh, to 29.5 in Coatbridge, 32.3 in Perth, and 39.1 in Dundee.

The 1086 deaths from all causes were 77 in excess of the number in the previous week, and included 147 which were referred to the principal epidemic diseases, against numbers rising from 92 to 128 in the three preceding weeks. Of these 147 deaths, 86 resulted from whooping-cough, 17 from scarlet fever, 16 from infantile diarrhoeal diseases, 13 each from measles and diphtheria, and 2 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 3.3, against 1.5 per 1000 in the large English towns. The deaths attributed to whooping-cough, which had increased from 28 to 82 in the six

preceding weeks, further rose to 86 last week, of which 47 occurred in Glasgow, 22 in Dundee, 6 in Edinburgh, 4 in Motherwell, and 3 in Greenock. The deaths referred to scarlet fever, which had been 9, 16, and 12 in the three preceding weeks, rose to 17 last week, and included 9 in Glasgow and 2 each in Edinburgh, Hamilton, and Clydebank. The fatal cases of diarrhoea and enteritis (among infants under 2 years), which had been 7, 8, and 15 in the three preceding weeks, further rose to 16 last week; 8 deaths belonged to Glasgow, 3 to Dundee, and 2 to Hamilton. The deaths attributed to measles, which had averaged 7 in the four preceding weeks, rose to 13, of which 11 occurred in Dundee. The deaths referred to diphtheria, which had been 10, 8, and 10 in the three preceding weeks, further rose to 13 last week, and comprised 4 each in Glasgow and Edinburgh, 2 each in Aberdeen and Paisley, and 1 in Ayr. The fatal cases of enteric fever were recorded in Glasgow and Edinburgh.

The deaths referred to diseases of the respiratory system, which had been 275, 238, and 272 in the three preceding weeks, further rose to 302 in the week under notice, and were 123 in excess of the number recorded in the corresponding week of last year. Thirty-six deaths were associated with different forms of violence, against 30 in each of the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,212,380 persons at the middle of this year, 661 births and 609 deaths were registered during the week ended Saturday, Feb. 6th. The annual rate of mortality in these towns, which had been 24.4, 24.0, and 24.7 per 1000 in the three preceding weeks, further rose to 26.2 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 25.2, against 19.1 and 23.1 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 30.5 in Dublin (against 21.5 in London and 22.7 in Glasgow), 25.2 in Belfast, 27.9 in Cork, 29.1 in Londonderry, 23.0 in Limerick, and 15.2 in Waterford, while in the 21 smaller towns the mean death-rate was 20.7 per 1000.

The 609 deaths from all causes were 34 in excess of the number in the previous week, and included 38 which were referred to the principal epidemic diseases, against numbers declining from 48 to 32 in the three preceding weeks. Of these 38 deaths, 13 resulted from whooping-cough, 10 from infantile diarrhoeal diseases, 6 from measles, 5 from scarlet fever, 3 from diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1.6, against 1.5 and 3.3 per 1000 in the English and Scotch towns respectively. The deaths attributed to whooping-cough, which had been 10, 9, and 11 in the three preceding weeks, further rose to 13 last week, of which 7 occurred in Dublin and 4 in Belfast. The deaths of infants (under 2 years) referred to diarrhoea and enteritis, which had been 14, 4, and 8 in the three preceding weeks, rose to 10 last week, and comprised 6 in Dublin, 3 in Belfast, and 1 in Larne. The fatal cases of measles, which had been 12, 15, and 4 in the three preceding weeks, rose to 6 last week, of which 4 belonged to Belfast. The 5 deaths attributed to scarlet fever were slightly in excess of the average in recent weeks, and comprised 4 in Belfast and 1 in Waterford. Of the 3 deaths referred to diphtheria, 2 occurred in Dublin and 1 in Cork. The fatal case of enteric fever was registered in Limerick. In addition to the above deaths, 3 fatal cases of typhus were recorded in Londonderry and 1 in Dublin.

The deaths referred to diseases of the respiratory system, which had been 164, 137, and 160 in the three preceding weeks, further rose to 172 in the week under notice. Of the 609 deaths from all causes, 173, or 28 per cent., occurred in public institutions, and 6 resulted from different forms of violence. The causes of 27, or 4.4 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the English towns the proportion of uncertified causes did not exceed 0.9 per cent.

THE IRISH ROYAL COLLEGES AND BELGIAN STUDENTS.—The Royal Colleges in Ireland have agreed upon two important concessions to Belgian medical students who are in forced exile from their own country. In the first place, the curriculum of the four Belgian Universities will be accepted as qualifying to sit for the examinations of the Conjoint Committee of the Royal Colleges. In the second place, the Conjoint Committee is authorised to remit the fees in the case of Belgian students who are unable to pay them.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Aid for the Belgian Doctors and Pharmacists.

At the request of Sir Rickman Godlee, Dr. Herbert A. Bruce, Toronto, has successfully organised a strong and representative committee of the leading physicians and pharmacists of Canada, having for its object the relief of Belgian doctors and pharmacists. The central committee is located in Toronto, where meetings are being held regularly and the work prosecuted with vigour. Dr. Walter McKeown acts as secretary and Dr. David Gibb-Wishart as treasurer. Its personnel consists of presidents of the national and provincial medical societies, presidents of the various Medical Councils, the editors of the medical journals, and the deans of the medical departments of the universities. Although just organised there has already been made a number of substantial contributions from the members of the professions in Toronto as well as from some private citizens.

Medical Reciprocity in Ontario with Great Britain.

Late in December a special meeting of the newly elected Medical Council of Ontario was called in Toronto, and the subject of medical reciprocity was fully discussed. It was resolved unanimously to approve of the principle of medical reciprocity; and the Legislative Committee of the Council was instructed to lay the matter before the Ontario Legislature for sanction, and also to bring the proposition before the General Medical Council of the United Kingdom. When Ontario falls in line that will make five provinces in Canada having reciprocity with the motherland—namely, Prince Edward Island, Nova Scotia, New Brunswick, and Quebec. It will only remain then for the four western provinces to complete the arrangement for all Canada.

The Canadian Medical Profession and the War.

It is reported that already Canada has 160 medical men serving the Empire either in England or at the front; and many more are in line for the front with Canada's second contingent. Many of the leading men have volunteered for service, and others have actually taken training. Altogether in Toronto, after the second contingent has been supplied, there is a waiting list of nearly 200. McGill Medical Department will send in the spring a complete hospital staff from the members of the medical faculty and the student body, the nurses being selected from the various hospitals of the city. Dean Birkett will be in command. Queen's University Medical Department, Kingston, Ontario, has also offered a complete general hospital. And now comes another offer from the French-Canadian medical men and students at Laval University, Montreal, for still another general hospital. Not only for active service, but for relief, the medical profession of Canada is well to the fore. An example of what medical societies are doing is seen in the case of a recently organised society in Toronto, the Æsculapian Club, of some 70 members. This society has practically donated all its reserve funds: to the Patriotic Fund, \$100; Ladies' Comforts for Soldiers Fund, \$50; Belgian Relief, \$200; and for surgical supplies to wounded in Northern France and Belgium, \$50.

Toronto University and German Professors.

The University of Toronto has been very much in the public eye during the past two or three months owing to having retained on its teaching

staff three German professors. One of the governors, a prominent financier, died suddenly, but left a letter which deprecated retaining these professors on the staff in war time, or of even permitting them to retain their connexion with the University, although released from their duties on full pay. Still another leading financier and public man, Sir Edmund Osler, protested, and resigned over the matter. The result has been the departure of two of the German professors for the United States, whilst the third remained in Toronto and took out naturalisation papers. So far that professor has been allowed to provide a substitute. This has brought the president of the University, whose rule is practically predominant, owing to recent legislation, into difficulties.

Queen's University and the War.

When the war began no university in Canada responded to the call so promptly or did so well as that of Queen's at Kingston. This was due to the splendid work of the Faculty of Applied Science. A company of engineers was sent to Valcartier, which was the only organised contingent at that camp. Of the work they did there professional soldiers and others qualified to speak have done so in the highest terms. With the second Canadian contingent another well-trained corps will go, being again the only Canadian university to send an organised unit. Of the 80 members of this unit 70 are members of the Kingston School of Mining, the other 10 being picked from the Faculties of Arts and Medicine.

THE VALUE OF TINCTURE OF IODINE AS A BACTERICIDE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Jan. 2nd Dr. Alexander Brown asks if the tincture of iodine, or a 2 per cent. solution, can destroy bacteria and their spores. Since there are several hundred varieties of bacteria recorded as excitants of disease, and as there may be wide differences in their resistance to antiseptics, much more experimental work must be undertaken before a comprehensive answer to Dr. Brown's inquiry can be given. The following experiments, which I made two years ago, though they offer a very partial answer to the question, may be of interest at the present moment. I had been asked by Dr. J. R. Bentley, of Limpsfield, to suggest a douche for a case of cystitis. The patient had had his prostate removed, to his great relief, but his cystitis persisted despite a partial relief from an autogenous vaccine of the *B. coli* present in his urine. The failure to clear up the infection was attributed to the sacculated condition of the bladder. An emulsion of living *B. coli*, obtained from a catheter specimen of the urine, was divided into six equal portions. To each portion an equal volume of solution of tincture of iodine in varying strengths, distilled water being the diluent, was added. Thus—

Tabule No. 1	= 2%	tincture of iodine in distilled water.
" No. 2	= 1%	" " " "
" No. 3	= 0.5%	" " " "
" No. 4	= 0.25%	" " " "
" No. 5	= 0.125%	" " " "
" No. 6	= 0.0625%	" " " "

These tubules were at once placed in the incubator at 37° for five minutes only and directly afterwards an equal volume from each was pipetted into a tube of gelose. The inoculated culture tubes were incubated at 37° for 24 hours and no growth occurred in any of them. The deduction was that the tincture of iodine solution, in each of six strengths (2 per cent. down to 0.0625 per cent.), had proved an effective bactericide. Irrigation of the bladder with 0.2 per cent. strength was recommended. This proved to be quite unirritating, and cultures taken on the following day showed marked diminution in the number of colonies of *B. coli*.

The coliform group of bacteria is a very large one, very widely spread, and plays a most important rôle in many infections, though perhaps not often the leading part. Its vitality in most strains is above that of many other common pathogenic microbes. Yet its resistance, if one may safely argue from the above tests, to iodine solutions falls far below that strength (tincture, or 2 per cent. solution) generally employed by surgeons.

Some years ago I had considerable experience of very severe accidents amongst the Durham miners. Extensive lacerated wounds, always badly contaminated with the highly septic pit dust, were very frequent, and I generally brushed them over freely with tincture of iodine. Where this was done subsequent occurrence of suppurating cellulitis was very rare. For bad compound fractures I preferred to rely upon free irrigation with 1 in 5000 solution of perchloride of mercury. The latter solution never let me down in major midwifery operations, under the most unfavourable sanitary conditions, even when puerperal septicæmia was epidemic in the district, provided that the uterus and vagina were thoroughly irrigated at the conclusion of the labour. When, in deference to various authorities, who said that perchloride was futile because it formed a surface coagulum, I abandoned my routine for other antiseptics I not infrequently had serious trouble.

With regard to the action of iodine upon spores, my experience is limited to a few of the common, innocuous bacteria of the spore-producing species. Some of the *B. vulgatus* family occur not infrequently as contaminations in the preparation of vaccines from throat cultures or from pyorrhæa. For three years I have made a practice of adding 0.5 per cent. of tincture of iodine to the emulsions after heating for an hour at 55° on three successive days. Subsequent cultures have invariably proved sterile, and I have attributed that sterility to the action of the iodine, since spores would probably have survived the comparatively low heat used.

I am, Sir, yours faithfully,

H. LYON SMITH, M.D. Durh.

Bentinck-street, W., Feb. 8th, 1915.

LICE AND RHEUMATISM AMONGST SOLDIERS.

To the Editor of THE LANCET.

SIR,—I have read with very great interest Sir Lauder Brunton's letter with this title in your issue for Feb. 6th, but among the remedies for body lice he does not mention paraffinum liquidum (B.P.), which can also be obtained in a crude state. The B.P. preparation is very largely used at our cleansing station in Poplar in the treatment of verminous children. After the bathing of the children liquid paraffin is

smear on the heads so that any lice may be killed as they are hatched from nits which have not been removed by combing the hair with a fine tooth comb dipped in methylated spirit or by application of the same by dabbing any discovered nits. If a little mercury perchloride, half grain to the ounce, is added to the spirit it makes the application more effectual. A very common household method of loosening the nit is the application of vinegar or acetic acid. Respecting Dr. S. Monckton Copeman's article on p. 273 of the same issue, I have known many mothers use the ordinary paraffin, but this is dangerous, the flash point being low, but that of liquid paraffin (B.P.) is high. Two handbills are circulated in the borough of Poplar re body and head lice, and the liquid paraffin (B.P.) is not only recommended for the head, but also, when dried after a bath, for gently rubbing over the whole body, except the face, leaving a thin layer of the liquid.

I am, Sir, yours faithfully,

FRED. WM. ALEXANDER,

Medical Officer of Health, Metropolitan Borough of Poplar.
Bow-road, E., Feb. 6th, 1915.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Feb. 6th you publish a letter from Sir Lauder Brunton under the above heading in which he enumerates 11 drugs as useful for the cure of the former and sulphur powder applied externally as a remedy for the latter disease.

In my book on "The Treatment of Diseases of the Skin," under the chapter on pediculosis, the following paragraph occurs on p. 169: "Sulphur wrapped up in a piece of flannel or in a porous bag and worn about the person next to the skin acts in many cases as a preventative." If our soldiers resorted to this very simple remedy they might remain free from both complaints.

I am, Sir, yours faithfully,

W. KNOWSLEY SIBLEY.

Cavendish-place, W., Feb. 7th, 1915.

THE SHORTAGE OF RESIDENT MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Feb. 6th Mr. W. M. Wilcox, secretary of the East London Hospital for Sick Children, suggests that there is a shortage of resident doctors. Perhaps if a reasonable payment be given the very "alleged" shortage will disappear. The local educational authorities now pay not less than £250 to freshly qualified doctors, while the equally fresh tuberculosis medical officers under the National Insurance Acts receive up to £350. I am told that about 3000 doctors have entered their names at the Admiralty and War Office. Each accepted will receive about £1 per day on service. May I add that many of the steamship companies are now paying their surgeons £15 to £20 per month, a bonus of £50 per annum, the right to charge fees to saloon passengers, and admission to membership for the pension fund. The present resident doctor at voluntary hospitals is paid a lost-dog's wage and is financially on the same degrading level as the Poor-law medical officer. Even residents in Poor-law infirmaries now obtain over £250 per annum, extra fees, with board, lodging, and washing—i.e., about £450. Let Mr. Wilcox attempt to do away with the dog-in-the-manger policy of doctors now acting as visiting

men to the voluntary hospitals and double the staff of such. This number can be increased by 10,000 in one week by appointing local district visiting staffs. At Liverpool the majority of the visiting doctors are entitled to charge full fees to hospital patients occupying pay beds and pay wards. Local doctors will not be excluded from making a fair wage if appointed. Only a little common sense is required to meet the "scarcity of doctors" bogey. Will the "men in possession" agree?

I am, Sir, yours faithfully,

Liverpool, Feb. 8th, 1915.

R. R. RENTOUL, M.D.

TUBERCULIN TREATMENT OF PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—In Dr. E. G. Glover's communication on this subject in THE LANCET of Feb. 6th occurs the following statement:—

There is one other point which deserves notice, although perhaps it is a minor one, and it is that the dangers noted after reactions—i.e., extension of disease, increased activity, pleurisy, and pneumothorax—are unfortunately, as the Registrar-General will testify, the dangers of the disease itself.

Such a remark has no bearing on the danger or otherwise of administering tuberculin. No sound critic of tuberculin ever imputed to tuberculin a capacity to do more than increase the disease, and because the disease spreads and produces the above results in many untreated cases, this in no way removes tuberculin from the list of agents which may hasten the above calamities.

I am, Sir, yours faithfully,

Ayrshire Sanatorium, Feb. 6th, 1915. EDWARD E. PREST.

LEECHES AND THE WAR.

To the Editor of THE LANCET.

SIR,—With regard to Mr. J. D. Marshall's offer in THE LANCET of Feb. 6th, it may be of interest to state that leeches of the official variety are obtainable to a limited extent through the ordinary trade channels at a cost less than one-fourth that mentioned by Mr. Marshall for *Limnatis granulosa*. This institution received a small number of leeches of French origin this week.

I am, Sir, yours faithfully,

London Hospital, Feb. 6th, 1915.

F. A. HOCKING.

** But the price of a leech might vary with its capacity.—ED. L.

THE DEARER LOAF.

To the Editor of THE LANCET.

SIR,—As a result of the appearance of your leading article with this title on Jan. 30th, I have been asked by the Corn Products Company, Limited, to forward you some loaves made from a mixture of wheat flour and cornflour. My son, Mr. William C. Jago, who now controls the Jago Laboratories, has had some loaves baked for me in a test bakery. Samples of these, numbered 1, 2, 3, and 4, were forwarded to you yesterday.

The following are particulars of the mixtures from which the respective loaves were made: 1. London Town household flour only, with salt, yeast, and water. 2. Mixture of 90 parts same flour with 10 parts cornflour; in addition gelatinised cornflour at the rate of 4 lb. to the sack of 280 lb., and dry corn starch sugar at the rate of 2 lb. to the sack were used. Other ingredients as before. 3. Mixture of 80 parts same

flour with 20 parts cornflour. Additions, &c., as in No. 2. 4. Mixture of 66 parts same flour with 20 parts cornflour and 14 parts peafLOUR. Additions, &c., as in No. 2. The volumes of the resultant loaves, each made from 560 grammes of the flour or flour mixture, were as follows: (1) 2839 c.c.; (2) 2676 c.c.; (3) 2593 c.c.; (4) 2022 c.c. The mixed flour loaves were all smaller than that from unmixed flour, but in every case they were of fair volume and good open texture. The loaves themselves will, however, best show you the general characters of the resultant bread. I think you will agree that in colour and general appearance Nos. 2 and 3 are fairly equal to No. 1, and would prove quite as digestible. The employment of No. 2 mixture would increase the available supply of breadstuffs from 100 parts to 111 parts, while in the case of No. 3 the increase would be from 100 parts to 125 parts.

In the case of No. 4 the object of the experiment was somewhat different—viz., to prepare bread that should have about the same protein value as the white flour used in the preceding mixtures. A sample of the flour yielded 10 per cent. of protein on analysis. Taking the protein content of peafLOUR at 25 per cent., a mixture of two parts of peafLOUR to three parts of cornflour would also contain 10 per cent. of protein, and might therefore be used in any desired proportion with the wheaten flour without altering its protein content. In the case of No. 4, two parts of wheaten flour were taken to one part of the pea and corn flour mixture. This represents a somewhat large addition to a flour which, to start with, was somewhat on the weak side. The dough was naturally very friable in the handling, but nevertheless made a fair loaf. Again, the sample itself will best show you the nature of the bread. (In all cases please make allowance for the staleness and effects of packing on the loaves when they reach you.) I think you will agree that this bread is not at all unpleasant in either appearance or flavour. Judging from its physical character I should say such bread would be very digestible and its proteins capable of very good absorption. In all probability the ratio of absorption would be slightly higher than is the case of the white bread. The use of such a mixture, if necessity arose, would raise the amount of available bread-stuffs from 100 to 150 parts and with no loss of nutritive value.

At present market prices the No. 4 mixture works out slightly lower in price than the flour. There is not likely to be any shortage in the world's supply of cornflour, and in addition to peas there are lentils and soya beans to draw on as auxiliary sources of protein. The latter especially is exceedingly rich in flesh formers, and yields a flour which is light in colour and of pleasant flavour.

I am, Sir, yours faithfully,

Hove, Sussex, Feb. 6th, 1915.

WILLIAM JAGO.

** The results are quite interesting. The loaves received appeared to us to be quite acceptable in regard to texture, flavour, and appearance.—ED. L.

LONDON UNIVERSITY EXAMINATIONS AND THE NEW PHARMACOPOEIA.—The regulations for the second examination for medical degrees, Part II., have been amended by the insertion of the following footnote: At the examinations in pharmacology held in March and July, 1915, students will be permitted to base their replies either on the old or on the new edition of the Pharmacopoeia provided that they shall be required to state on which edition such replies are based. In and after March, 1916, replies must be based on the new edition of the Pharmacopoeia.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE Fund has during the week received a fair number of subscriptions, conspicuous among them being a cheque from the Ontario Medical Association for £102 13s. 4d.

The Liverpool subscriptions, which for the present remain in the hands of the Liverpool Medical Institution, have continued to come in, and a vigorous start is being made in Manchester under the auspices of a strong local committee.

CENTRAL EXECUTIVE COMMITTEE.

Certain cases of distress have been relieved immediately, on the representation of Dr. Clément Philippe, the President of the Société Belge de Médecine et de Pharmacie en Angleterre, and there has been some success in finding work for Belgian practitioners, under the recent privilege of British registration. It seems doubtful whether the General Medical Council will be able to reduce or remit the fees of Belgians desiring to register, and it may devolve upon the Fund to advance the money in some cases. There was no Belgian doctor found to fill a post where a single man was required, all the available Belgian practitioners being married. The receipts of garments, both for men and women, at 3, Hyde Park-street, London, W. (Dr. Philippe's house, kindly lent for the purpose), have been satisfactory, and the hours of distribution have been arranged as follows: Wednesday, 10 A.M. to 12 noon for men, and Friday between the same hours for women.

The case of surgical instruments designed for Belgium, and reported last week as being at the Tunnel Wharf, Rotherhithe, has been forwarded to Brussels, *via* Rotterdam, in the s.s. *Vesuvie*, which sailed on Feb. 1st.

THE MANCHESTER COMMITTEE.

An important committee has been formed at Manchester, and a circular is on the point of being issued to the local members of the medical and pharmaceutical professions setting out the position of their Belgian colleagues. The circular is signed by Dr. Alfred Brown, President, Manchester Pathological Society; Mr. J. Gray Clegg, President, Manchester Clinical Society; Dr. Archibald Donald, President, Manchester Medical Society; Mr. James Grier, President, Manchester Pharmaceutical Association; Dr. T. Arthur Helme, President, Manchester Medico-Ethical Society; and the following members of the central committee: Sir William Milligan, Professor G. Elliot Smith, and Mr. William Thorburn. Dr. E. M. Brockbank, Northern Assurance Buildings, Albert-square, Manchester, and Mr. Tom Miller, pharmacist, 5, Yarrow-street, Whalley Range, are acting as honorary secretaries.

Subscriptions may be sent to either of the secretaries, who will acknowledge their receipt and pass them on to the Central Fund. They will also be acknowledged in the medical and pharmaceutical papers. Cheques should be crossed "Lancashire and Yorkshire Bank, Limited."

Contributions of surgical instruments likely to be of use to the Belgian doctors may be sent to the Library of the Medical Society, University of Manchester, where they will be sorted and sent on to London.

The Manchester Committee propose also to appeal to the public through the lay papers.

THE FUND OF THE LIVERPOOL MEDICAL INSTITUTION.

The following is the second list of subscriptions which have been collected by the Liverpool Medical Institution:—

	£	s.	d.		£	s.	d.
Dr. G. A. Grace-Calvert	5	5	0	Dr. C. Alston Hughes	1	1	0
Dr. John E. Gemmell	5	5	0	Dr. W. Hardy Fleetwood	1	1	0
Dr. R. Wyse	5	0	0	Dr. R. Paterson	1	1	0
Dr. A. S. Parkinson				Dr. A. F. Seacome	1	1	0
(second subscription)	4	4	0	Dr. W. Macfie Campbell	1	1	0
Dr. J. E. Stott	2	2	0	Dr. John Robson	1	1	0
Dr. J. C. M. Given	2	2	0	Dr. H. Wycliffe Fisher	1	1	0
Dr. A. A. Mussen	2	2	0	Dr. David Morgan	1	1	0
Dr. A. C. E. Harris	2	2	0	Dr. W. Sanderson	1	1	0
Dr. A. C. Wilson	2	2	0	Dr. O. F. Evans	1	1	0
Dr. Walter C. Oram	2	2	0	Dr. F. F. German	1	1	0
Dr. J. F. Gordon	2	2	0	Dr. Albert E. Davis	1	1	0
Dr. T. Glynn Morris	2	2	0	Dr. Isaac Harris	1	1	0
Dr. T. B. Grimsdale	2	2	0	Dr. A. A. Meeson	1	1	0
Dr. A. E. Hawkes	2	2	0	Dr. E. I. Claxton	1	1	0
Dr. W. Morland Hocken	2	2	0	Dr. R. G. Sheldon	1	1	0
Dr. G. S. Stansfield	2	2	0	Dr. W. Cash Reed	1	1	0

Professor J. M. Beattie	2	2	0	Dr. R. Lucius Wood	1	1	0
Mr. Arthur Evans	2	2	0	Dr. J. J. Tisdall	1	1	0
Dr. Harriet Jones	2	0	0	Dr. F. Ingall	1	0	0
Dr. Douglas Moffatt	1	1	0	Dr. A. C. Lewis	0	10	6
Dr. Bennett Jones	1	1	0	Dr. N. H. Blair	0	10	6

The Liverpool Belgian Doctors' Relief Fund is intended for the relief of Belgian doctors, and we are informed that the Liverpool Chemists' Association is forming a local fund for the relief of their professional colleagues. The money in the hands of the Liverpool Medical Institution amounted on Feb. 4th to £382 10s. 3d. The Fund is still open, and subscriptions should be sent to Dr. T. R. Bradshaw, at the Institution, 65, Rodney-street, Liverpool.

THE DURHAM AND NEWCASTLE DISTRICT.

Dr. A. S. Percival, 17, Claremont-place, Newcastle-on-Tyne, who is acting as one of the joint secretaries of the movement in this district, has written to the constituency in the following terms:—

"We are under a lasting obligation to Belgium for her magnificent stand against the German invaders; indeed, it is an obligation that can never be fully repaid, and it should be regarded as a privilege to have this opportunity of showing our sympathy with our fellow practitioners. Chiefly with this end in view a meeting will be held at the College of Medicine, Newcastle-upon-Tyne, on Wednesday next, Feb. 17th, at 4 P.M. An address will be given by Professor Jacobs of Brussels, who will give evidence of certain startling facts that for ruthless and savage barbarity have no equal. All doctors and pharmacists are invited to attend the meeting, at which it is proposed to form a committee for dealing with Belgium's appeal. Meantime, any subscriptions that are sent to me in aid of the Fund will be gratefully acknowledged and duly reported in the medical journals."

THE WEEK'S SUBSCRIPTIONS.

The subscriptions received by Dr. Des Vœux up to Tuesday evening last, in addition to those previously acknowledged, amounting to £5000, and not including money received by the Scottish or Irish Funds, are as follows:—

	£	s.	d.		£	s.	d.

The War.

THE TROOPS AND ANTITYPHOID INOCULATION.

REFERENCE is made in our Parliamentary Intelligence this week to a leaflet on the subject of anti-typhoid inoculation which is being distributed to the troops. The leaflet is addressed "To All Soldiers," and Lord Kitchener himself supplies a preface in these words:—

"I commend to the careful attention of every Soldier the following statement, to which, in the interests of the health of the Army, I attach great importance.—KITCHENER, F.M."

The statement is as follows:—

In every campaign typhoid fever is a serious element. In the South African War there were many more casualties from typhoid fever than from wounds.

In the present war the best is being done to prevent typhoid fever by extreme precautions in the matter of water-supply, as well as other sanitary measures, but in spite of this a number of men have been affected by the disease.

Inoculation Gives the Body Power to Resist Infection.

It is a means of protection in the efficiency of which those who have studied the question have complete confidence.

Inoculation has nothing to do with vivisection.

The great value of inoculation is shown clearly in the following figures:—

Of the 421 cases in the present campaign among British troops, 305 cases were in men who were NOT INOCULATED within two years.

In the 421 cases there have been 35 deaths

Of these deaths 34 were men who had NOT BEEN INOCULATED within two years.

ONLY ONE DEATH OCCURRED AMONG PATIENTS WHO WERE INOCULATED, and that man had only been inoculated once, instead of the proper number of times—namely, twice.

For your own sake, for your country's sake, and for the sake of the Army you should not fail to avail yourself of the protection secured by this simple, safe, and well-tested measure.

Medical officers are always ready and anxious to inoculate any soldier at any time, and the greatest care is taken in doing so. With proper care it has never been known to do a man harm.

The statement, which seems to be worded in just the right way to impress a soldierly audience, is signed by Sir Thomas Barlow, President of the Royal College of Physicians of London; Dr. A. H. Freeland Barbour, President of the Royal College of Physicians of Edinburgh; Sir W. Watson Cheyne, President of the Royal College of Surgeons of England; Dr. E. MacDowel Cosgrave, President of the Royal College of Physicians of Ireland; Mr. F. Conway Dwyer, President of the Royal College of Surgeons in Ireland; Mr. J. W. B. Hodson, President of the Royal College of Surgeons of Edinburgh; and Sir Frederick Treves, Sergeant Surgeon to H.M. the King.

THE CASUALTY LIST.

The official casualty lists published since our last issue have contained the name of one medical officer, Captain James Alexander Terras Bell, M.D., New Zealand Medical Corps, reported as having died in Egypt.

MEDICAL PRECAUTIONS AGAINST AIR RAIDS.

In an annotation with the above title in THE LANCET of Jan. 9th the surgical aspects of an air raid upon London were briefly discussed, and it was stated that a scheme of preparation against such an outrage had been carefully thought out. With the sanction of the military and police authorities this scheme has now been elaborated and

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund and crossed Lloyds Bank, Limited. These will be acknowledged by post direct, and a list will appear in THE LANCET weekly.

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries acknowledges with thanks the receipt of surgical instruments kindly contributed by the following donors since the publication of the last list:—

Anonymous, per the Oldham Medical Society; Dr. W. L. W. Marshall, Huddersfield; Dr. G. W. Collins, Wanstead, Essex; Dr. Cosgrave George, Colwyn Bay.

extended to include vulnerable places on the coast. The committee of the Royal Society of Medicine, which has been occupied with the medical side of the matter, has now organised a service of surgeons, anaesthetists, and dressers, ready to proceed at once in self-contained units to any point where their services are required, travelling either by motor-car or by special train according to the needs of the occasion.

THE DISLOCATION OF MEDICAL SERVICE.

A meeting of medical practitioners and senior students was held in the Royal College of Surgeons, Edinburgh, on Monday last, when Mr. Hodsdon, President of the College and chairman of the meeting, spoke forcibly on the situation of civilian practitioners. Many civil practitioners, he said, had attached themselves to various units, and were willing to spend their spare time in military duties, but they were not prepared and did not anticipate that they would be called away from their practice at a moment's notice. At that moment there were men who had not been back to their practice since they were called up during the mobilisation in August. The Scottish Medical Service Emergency Committee had assisted medical men who were with the colours, while at the instance of the General Medical Council the War Office had now made exchanges possible whereby the Scottish practitioner might find himself back in his own town.

Dr. Norman Walker, convener of the Scottish Medical Service Emergency Committee, said that the work of the committee had extended far beyond that of merely introducing assistants or locum tenents to men who wanted them. The dislocation of medical practice in the country had increased, and was still increasing, and if they were to avoid a serious breakdown in the medical service in Scotland they must realise the situation, for more demands would be made upon them, and the supplies would have to be very carefully husbanded if they were to meet that demand. They had to supply recruits for two armies—one the King's forces, and the other the standing army for home defence against the constant enemies, disease and death. It was because doctors were as necessary in the army and navy as engineers, gunners, and air-men that it was incumbent on the medical profession to supply the wants of the King's forces. Something over one-sixth of the medical profession were already serving—nearly 7000 out of a total of 37,000—and more were required, for the day was not far distant when six figures would not cover the number of our forces abroad. Seeking where the additional doctors were to come from, Dr. Norman Walker hoped no licensing body, from a sort of morbid patriotism, would admit to the profession insufficiently trained students. The student's business was to work hard, and the teacher's to give more care to his teaching than he ever gave before, so that the student should complete his course in the shortest possible time and then offer his services to the country if there were no valid reason against this course. But if such reason existed it must be remembered that a man still served his country if, by undertaking the work of one who had gone, he so loyally respected his interests that the other went with an easy mind. But the country districts were crying out for doctors, and before many weeks passed they would be very near the Trade Unionist Paradise—"two jobs for every man." Dr. Norman Walker concluded

by referring to the new Army Order permitting exchanges, and begged that it should be taken advantage of by medical men.

Principal Sir Donald MacAlister acknowledged how cordially, as soon as it understood the difficulty they were in as regards civil practice, the Army Medical Service responded in the only way they were able to respond. It was quite clear that the civil service must dispense with its ordinary superabundance of practitioners if the army was to be supplied, and the question was whether a proper reorganisation of the civil service could be achieved. For the first two or three months it looked as if it could be done without much difficulty, but difficulties that seemed at first not impossible were becoming almost impossible to overcome, and it was quite certain that the civil community would have to do with a good deal less doctoring if they were to keep the army supplied, as it ought to be supplied, with doctors. They had better face the situation now, he urged, before in some areas the medical service altogether broke down. He believed that by a redistribution of their forces there could be provided a respectable medical service for all the civil population, but the worst of it was that while there was a superabundance in some places there was a very deficient service in others. He did not see any other machinery in existence for attempting the difficult problem of organising a redistribution than the Emergency Committee. A certain number of Belgians would be available, and the reciprocal privilege of practising in Belgium after the war would be no small one. He believed there were also coming to this country about 100 Canadian registered surgeons and a certain number from Australia and India.

The gist of an important meeting was to show that the shortage of medical men is expected in the best-informed circles to become more serious.

UNIVERSITY OF LONDON: SPECIAL LECTURES IN MILITARY HYGIENE.—With the concurrence and assistance of the Army Council a course of nine lectures on "The Health of the Army in the Field" will be given at the Royal Army Medical College, Millbank, S.W., by Major P. S. Lelean, R.A.M.C., F.R.C.S., D.P.H., at 5 P.M., on Feb. 22nd, 24th, and 25th, and March 1st, 3rd, 5th, 8th, 10th, and 12th. The course will form an introduction to the problems of hygiene of forces in the field, for (i.) qualified medical men without military experience; (ii.) combatant officers about to proceed to the front; and (iii.) others interested in the subject (provided the accommodation is sufficient). In the allocation of tickets preference will be given in this order. A detailed syllabus will be available for the lectures, at which the following matters will be dealt with: hygiene of active service, sickness in the army, organisation and administration in the field, water and water-supplies, and conservancy on active service. Arrangements will be made, if desired, for visits of inspection to a typical camp. Applications for tickets should be made to the Academic Registrar, University of London, South Kensington, S.W., and be accompanied by remittance of the fee of £1 1s. Applicants should indicate whether the tickets are required for (1) medical men; (2) combatant officers proceeding to the front; or (3) other persons. Tickets will not be despatched before Feb. 15th.

DENTAL AID FOR THE TROOPS.—A circular letter was issued by the War Office to the various commands on Jan. 22nd with reference to the subject of dental aid for the troops. In this it is announced that, as a temporary measure for the period of the present war only, the existing system whereby a sum of money is allotted to each command for the dental treatment of recruits and serving soldiers will be held in abeyance. During the war all dental treatment necessary to render a non-commissioned officer or man fit for service in the field will

be afforded, including the provision of such artificial dentures as may be considered necessary for efficient mastication. The existing limit of one pound (£1) per man may be exceeded in cases where the work necessitates a higher expenditure, provided that in no case is the expenditure to exceed three pounds (£3) per soldier treated without the special authority of the general officer commanding-in-chief. Where available dentists attached to military hospitals will be employed to the fullest extent. For the supply of artificial dentures the following scale of fees is given as a guide to the maximum cost, having regard to the class of work required: (a) Complete upper or lower denture from £2 to £3; (b) complete upper and lower dentures from £4 to £6; (c) partial upper or lower denture, comprising not more than five teeth, about £1 10s., or possibly a little higher.

EDINBURGH IN WAR TIME.—Our Edinburgh correspondent writes: "The Committee of Management of the Triple Qualification of the Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow have announced to students who have undertaken approved service with His Majesty's Forces that applications for partial recognition of such work in lieu of curriculum will be individually considered. Steps will be taken in each case to grant such concessions as appear to the committee to be in accordance with the recommendations of the General Medical Council.—Twenty-nine convalescent sailors from the hospital at South Queensferry, most of whom had been wounded in the recent North Sea fight, were removed on Feb. 3rd by ambulance train to the Marchioness of Bute's auxiliary hospital at Mount Stuart, in the Island of Bute. At Gourock the men were embarked on the Caledonian Company's steamer, the *Duchess of Bute*. Two ambulance wagons were supplied by the Red Cross Society in Edinburgh, and taken by train and boat to Rothesay, for the comfortable conveyance of the seamen to Mount Stuart House. Meals were provided *en route*, cooks being provided on the train by the Red Cross Society. After an appreciable interval, which presumably reflected in some degree the comparatively quiet spell at the front, another hospital train arrived in Edinburgh on the night of Feb. 5th, bearing its burden of 100 wounded soldiers. The wounded were received at the Caledonian Station by the Red Cross workers, with their usual equipment of motor ambulances and motor-cars, and were conveyed to Dalmeny House and the Deaconess Hospital."

A NEW ARMY HUT.—Mr. H. A. Pritchard, A.R.I.B.A., of Cardiff, has designed a hut for the accommodation of soldiers which is now on view at the College of Ambulance, 3, Vere-street, London, W. It is built of wood of standardised lengths, and can therefore be turned out from the saw-mill ready for erection. The outside of the hut is covered with a durable waterproof material which ensures dryness and warmth, and in hot weather would prevent the scorching heat attendant upon corrugated iron. The whole appearance of the hut is like the roof of a dwelling-house, the sides of the roof reaching almost to the ground, whilst at the gable ends are the door and windows at one side and a large window at the other. The hut measures 22 ft. long, 14 ft. wide, and the highest point of the sloping roof is 15 ft. from the ground. The whole hut is raised from the ground some 12 in. on concrete blocks so that there is ample ventilation beneath the oak flooring. The hut can accommodate 14 men, or as many as 16 at an emergency. The ventilation is free and the light ample. The whole hut is collapsible and can thus be easily transferred by road or rail, and can therefore be used by an army on the march as part of its equipment for offices, sleeping accommodation, or for a temporary hospital. The free space in the centre affords room for men to use the hut as a bed-sitting-room. The cost of the hut completed is about £100. There are many ingenious devices which add to the benefits of the hut. Before the door is a "door-mat" consisting of a wooden grill on which the men can get rid of the mud from their boots, which renders huts of this kind like quagmires as a rule. To the upright poles in the hut a movable table is attached, which can be used for a mess-table, or an operating-table if the hut is used as a hospital. Special

arrangements for storing utensils, food, &c., are in evidence above the level of the men's heads. Outside at either end of the hut where the roof slopes to the eaves a wide gutter trough receives the water from the roof and from which the water can be run off, or the whole trough can be lifted, placed on supports, and used for washing purposes by a number of men at a time. Instead of the water being allowed to run down to the eaves and the trough, it can be diverted by placing a wooden rod obliquely across the sloping roof, whereby the water is made to issue at one side of the roof, a few feet above the ground, where it can be collected in basins, pails, &c., for future use. Mr. Pritchard's device seems not only ingenious but eminently useful for practical purposes; and the favourable comments passed upon the hut by officials and visitors on Saturday, Feb. 6th, when the hut was inspected at the College of Ambulance, promise well for its success.

AMERICAN WOMEN'S WAR HOSPITAL.—The American Women's War Hospital at Paignton is being enlarged by 30 beds, bringing the total capacity of the hospital up to 230. This addition has been made possible by utilising the fine Riding School. The new ward will be called "St. George" Ward, after a generous donor to the fund, and when completed will be staffed by English and American nurses, as are all the other wards in the hospital.

A RECORD OF ATROCITY.—In the *Field* this week Dr. Arthur Tacquin, physician-in-ordinary to the King of the Belgians, tells the story of German cruelty, insolence, pillage, and arson exactly as it came under his own eye, with photographs taken by himself. The proclamations which the enemy has scattered through Belgium are many of them given in full in a terrible supplement to the great sporting newspaper, and the editorial summary which introduces the startling pictures and text is a red-hot indictment of German crime written in convincing terms.

Medical News.

UNIVERSITY OF DURHAM (COLLEGE OF MEDICINE), NEWCASTLE-ON-TYNE.—At the annual meeting of the Council of this College held on Feb. 9th an illuminated address, in Latin, was presented to Professor Sir G. H. Philipson, M.D., the President of the College, congratulating him on the completion of his 50 years' service to the College. The address called attention in the following terms to his varied and eminent services: "Quis enim nostrum ignorat te pathologiae doctrinam, medendi scientiam atque usum, epistularum academicarum commercium, totius denique Collegii regimen, pari deinceps cum diligentia et humanitate curavisse?"

DONATIONS AND BEQUESTS.—By the will of the late Mr. William Long, of Gloucester, the testator has left £10,000 to the Gloucester District Nursing Society and £3000 to the Gloucester Provident Dispensary.—The late Mr. William Ransom, of Hitchin, has bequeathed £500 to the North Herts and South Beds Hospital.—The late Major W. Barrett, of Moredon, Somerset, has left by will £1000 to the Taunton and Somerset Hospital for the endowment of a bed.

BADGE FOR THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At the last meeting of the Royal College of Physicians of Ireland the ex-President, Dr. C. E. FitzGerald, asked permission to present to the college an official badge to be worn by the President on ceremonial occasions. He wished to commemorate the fact that in his person the college had for the first time elected an ophthalmologist to its highest office. The college gratefully received the gift.

MEDICAL MAGISTRATE.—Dr. William Dunn has been made a Commissioner of the Peace for the county of Rutland.

Dr. Stanley Riseley, until recently ophthalmic surgeon to the Royal Hospital, Sheffield, has died at the early age of 47.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Parliamentary Session.

PARLIAMENT is again in session, and it is expected to sit continuously for four or five weeks. All its attention is being given to problems arising out of the war. Matters of party controversy are not being dealt with.

The Inoculation of British Troops.

Very considerable attention has been given in the House of Commons within the past few days to the subject of the inoculation of British troops against typhoid. There are three distinct sets of opinion on the subject. A very large body of members think that all future recruits who join the army should do so on the express condition that they should undergo inoculation, and that all soldiers who are already in the ranks and refuse to submit to the operation should either be allowed to retire or be allocated to home defence work. No uninoculated men should go to the front. The second set of opinion is that the present system of voluntary inoculation should continue, but that every means of persuasion short of coercion should be exerted to induce men to be inoculated. This view admits the value of the operation, but would leave an option with the individual. The third set of opinion is that of the anti-inoculation party, which is very small numerically. Its activities have been directed to drawing attention to cases in which it alleges illegitimate pressure has been exerted on soldiers to coerce them into undergoing inoculation. In these circumstances it is most important to watch the attitude of the Government and of the War Office. Mr. TENNANT, the Under Secretary for War, stated in the House of Commons this week that the evidence was accumulating in favour of the inoculation of our troops. The matter of making it compulsory was under consideration, and he hoped to be able to give a definite answer shortly. Some highly significant statistics showing the beneficial effect of inoculation against typhoid in the present war have been given to Parliament in the course of the last few days.

HOUSE OF COMMONS.

THURSDAY, FEB. 4TH.

Treatment of Mental Strain amongst Soldiers.

Mr. DUNCAN MILLAR asked the Under Secretary for War whether steps had been taken to secure that the treatment of soldiers and sailors suffering from mental strain should be carried out in hospital wards or other institutions not under lunacy administration, so as to avoid sending all such cases, which were not certifiable, to asylums.—Mr. TENNANT replied: Every endeavour is being made to treat patients suffering from traumatic neurasthenia and cases of mental strain in such a manner as to avoid sending those not certifiable into asylums. For this purpose arrangements have been made to treat such cases in certain private and civil hospitals in the United Kingdom, and a Red Cross Military Hospital has been opened in Lancashire for their reception. This latter hospital is administered by and the patients are under the care of medical officers holding commissions in the Royal Army Medical Corps.

Mr. DUNCAN MILLAR: Is the War Office prepared to make a grant for equipment?—Mr. TENNANT: I do not think so.

Inoculation against Enteric Fever.

Mr. LAURENCE HARDY asked the Under Secretary for War whether he was aware of the campaign which was in existence for the purpose of discouraging our soldiers in the new armies from being inoculated against enteric and other similar diseases; whether, in view of the statistics in support of inoculation, as shown during the present war, measures would be at once taken against any organisation which carried on such an agitation; and whether he would consider whether the time had now come when inoculation should be made compulsory for all soldiers proceeding to the front on active service, both for their own sakes and those with whom they were in contact.

Mr. PETO also asked the right honourable gentleman whether inoculation against typhoid fever and vaccination against small-pox would in future be compulsory for all ranks in the military forces of the Crown before they were sent on service over-sea during the currency of the present war.—Mr. TENNANT (replying to both questions) said: The answer to the first point in the question of the honourable Member for Ashford (Mr. L. Hardy) is in the affirmative, and to the second is that it is not proposed to take any action against the organisations referred to. As regards compulsion, I am advised that legislation would be necessary. The introduction of a Bill is not at present contemplated, though this may be further considered should necessity arise.

Pay of Medical Officers in the Territorial Force.

Mr. STEWART asked the Financial Secretary to the War Office whether medical officers in the new army were paid £1 4s. a day, whereas medical officers who had served for years in the Territorial Force, and who had now volunteered for service anywhere, received only 15s. 6d. a day; and whether he could see a way to remedy the grievance of the Territorial service by putting them on the same scale of pay as the surgeons in the new army.—Mr. H. BAKER: I would refer the honourable Member to the answer which I gave to the honourable Member for the Bridgwater Division of Somerset on August 27th last.¹

Pay of Indian Medical Service Officers on Active Service.

Mr. RAWLINSON asked the Under Secretary for India whether his attention had been called to the reduced rate of pay of doctor of medicine officers of the Indian Medical Service who were now on active service with field ambulances; and whether he could see his way to raising their pay to the amount which they would receive if they were working for the Indian Medical Service in India during times of peace.—Mr. C. ROBERTS wrote in reply: Subject to certain exceptions which are at present under discussion with the Government of India, officers of the Indian Medical Service withdrawn from their ordinary duty for active service receive not less than the military pay and allowances ordinarily attached to their rank and position, and in some cases special higher rates provided for field service appointments. The Secretary of State recognises that the rules may sometimes entail loss of emoluments to Indian Medical Service officers withdrawn from civil appointments, but liability to recall to military duty is a well-understood condition of civil employment in the case of the Indian Medical Service, and he sees no sufficient reason for modifying the rules.

MONDAY, FEB. 8TH.

Antityphoid Inoculation in the British Army.

Mr. PETO asked the Under Secretary for War whether he could furnish particulars of any case of death from inoculation against typhoid fever.—Mr. TENNANT replied: So far as the War Office is aware there has been only one death which can be in any way connected with inoculation. This case was that of Corporal Nichols, of the 3rd Battalion (Reserve) City of London Regiment. I stated in this House on Nov. 27th last that the cause of death was pneumonia, but when the death certificate was received it was seen that the cause was given as (1) antityphoid vaccination and (2) pneumonia. The case has been investigated and submitted to Sir William Osler, who considers that death was due to an eight miles march which the man took within 24 hours after inoculation and not to the inoculation directly. Instructions have been given that care must be taken to see that men recently inoculated are not given hard work until their condition justifies their undertaking it without risk.

Mr. PETO asked the Under Secretary for War whether he could state the number of cases of typhoid, and deaths from typhoid, among inoculated men and uninoculated men in the Expeditionary Force from the commencement of the war to a recent date.—Mr. TENNANT answered: Of the 421 cases of typhoid in the present campaign among British troops 305 cases were in men who were not inoculated within two years. In the 421 cases there have been 35 deaths. Of these deaths 34 were men who had not been inoculated within two years. Only one death occurred among patients who were inoculated, and that man had only been inoculated once instead of the proper number of times—namely, twice.

Mr. CHANCELLOR asked the right honourable gentleman whether the punishment for refusing inoculation of men who had fought at the front by depriving them of the five days' leave to visit home which was granted to inoculated men was a form of influence and persuasion sanctioned by the War Office to induce men to undergo an operation which was not compulsory or legally enforceable and to which they had a conscientious objection; and whether men who stood upon the legal right guaranteed by the public announcements of the Minister for War were to be punished indefinitely for doing so by the refusal of the leave granted to others, or whether this action on the part of officers would at once be put an end to by a General Order issued from the War Office.—Mr. TENNANT said in reply: I am not aware of any case where a man returning from the front has been punished in the manner described in the question. The danger of infection being spread in the army by uninoculated men is considerable, and has to be guarded against by precautions being taken as regards granting them special leave. Any General Order will be in this sense.

The Health of the Army.

Speaking on the motion that the Speaker should leave the chair in order that the House might go into committee on army estimates, Mr. TENNANT (Under Secretary for War),

¹ THE LANCET, Sept. 5th, 1914, p. 677.

in the course of his observations, said: I should not like to conclude without saying a few words upon certain aspects of the medical treatment of the wounded in France. I do not think there is much that I can add to the narrative which I gave to the House in November last of the methods adopted by the Royal Army Medical Corps in bringing the wounded from the front to the clearing stations, thence to the base hospitals, and finally home here. Important as those functions are, the prevention of disease is even more important, and that is rightly regarded as the primary function of this corps. I think that I am right in saying that this is the first war in which we have been engaged in which an organised sanitary service has existed. We owe the establishment of this service to my noble friend Lord Haldane. Since its establishment we have been gradually perfecting its organisation during the last five or six years. When we look back to the fact that during the Napoleonic wars only 3 per cent. of deaths among our troops were due to wounds and 97 per cent. due to sickness or disease, and when we also remember the fact that during the Crimean War more deaths occurred from disease during the first three months than during the whole of the rest of the campaign, it is impossible to lay too much stress upon this preventive function of the Royal Army Medical Corps. How has this function been carried out? I have to thank my honourable friend the Member for the Holmfirth Division of Yorkshire (Mr. Arnold) for the very interesting and able report which he made to me after a visit which he paid to Paris, during which he got a great many figures. All the evidence which my honourable friend brought, and which comes to me officially, goes to show that by far the greatest amount of sickness amongst our soldiers at the present moment is due to the wet and the cold. Frost-bite and rheumatism are, I am sorry to say, very prevalent. We have issued from the War Office through the Army Medical Department a small leaflet to officers and non-commissioned officers telling them how to prevent frost-bite amongst their men. My honourable friend reports to me that, assuming the conditions of exposure of officers and men to be identical, frost-bite is three times as prevalent amongst the men as it is amongst the officers. I do not suppose that it is possible to assume that the conditions are quite identical, but you may be certain that the exposure of the men is not three times as great as that of the officers. My honourable friend presumes that this result is due to the officers having better boots, leggings, and equipment generally. If that is so, it proves that there is a certain amount of preventability of frost-bite, and I hope by the steps which we are now taking that this disease may be prevented to a larger extent than has been the case in the past.

The Question of Compulsory Inoculation.

Coming now to the question of enteric fever (continued the right honourable gentleman), I am glad to say that cases of this disease are luckily rare, and they have occurred almost entirely among the uninoculated. The evidence is accumulating in favour of making inoculation compulsory. This is one of those subjects which ought to be settled without prejudice. My honourable friend the Member for Holmfirth, who gave me this most interesting report, strongly holds that inoculation against typhoid ought to be made compulsory. It is for the House to say what they think upon this matter. I gave the House figures to-day on this subject in answer to a question, and they have been published in a leaflet to all soldiers with a prefatory note by the Secretary of State for War (Lord Kitchener), impressing upon all soldiers the great importance of inoculation.

Lord CHARLES BERESFORD: Does every soldier get one?

Mr. TENNANT: Yes, it is sent to every soldier.

Lord CHARLES BERESFORD: Is it put up in the recruiting offices?

Mr. TENNANT: Very likely. I have not time to go in detail into all the preventive measures taken by the Royal Army Medical Corps, but I should like to mention the sanitary squads, the water purifying sections, and the travelling hygiene and bacteriological laboratories, to which I drew attention in my speech in November. This is an entirely new feature, and these branches in particular are doing extraordinary and valuable work. Lastly, the Sanitary Commission sits at the War Office to advise the Secretary of State upon all matters relating to the health of the troops at home and abroad. What I have said relates to the army abroad, and it may be asked what we are doing for the health of our troops at home. Owing to the almost entire absence of the regular Army Medical Service engaged upon field operations certain difficulties have arisen, but thanks to the patriotic eagerness of the medical profession we have been able to obtain a high degree of efficiency. I cannot claim that complete efficiency has been achieved, but day by day the ideal is being approached. The new Army Medical Corps for the new armies are now in course of formation, and I believe they will be able to do excellent work should the occasion arise.

Vaccination of Soldiers.

Mr. TENNANT informed Mr. THOMAS that it was not considered advisable to alter the present rules governing the vaccination of soldiers joining the army.

Territorial Medical Officers.

In reply to Mr. W. GUINNESS, Mr. BAKER (Financial Secretary to the War Office) said: There is no difference in the pay of officers holding temporary and permanent commissions in the Royal Army Medical Corps, Territorial Force. The rate for captain is 15s. 6d. and for lieutenant 14s. a day.

Antityphoid Inoculation in Canadian Contingent.

Mr. TENNANT informed Mr. PETO that 95 per cent. of all ranks of the Canadian Contingent had been inoculated against typhoid.

The Anti-inoculation Campaign.

Sir J. D. REES asked the Attorney-General whether the Government could and would proceed under the Defence of the Realm Act against persons who incite soldiers to decline to submit to antityphoid inoculation.—Sir JOHN SIMON replied: The matter is under the consideration of the military authorities.

Inoculation of Soldiers against Typhoid Fever.

In the course of the debate in committee of supply on army estimates, Mr. CHANCELLOR drew attention to the inoculation of troops. He said that assurances had been given in Parliament by representatives of the War Office that no compulsion should be applied to soldiers to compel them to undergo inoculation. Those assurances had not been reflected in certain instances in the action which had been taken by officers. They had, by depriving men of privileges and in other ways, sought to coerce them to submit to this operation against their wishes. He did not complain about the inoculation of troops, nor did he complain of proper and legitimate methods of persuasion. But he did object most strongly to the coercion and compulsion which had been applied to men who had conscientious objections, and he hoped that officers who exerted compulsion and coercion would be reprimanded. The man had a right to refuse to be inoculated.

Mr. G. H. ROBERTS stated that he had taken part in the recruiting meetings, and he had told men on certain occasions that the Government had given an assurance that inoculation was not compulsory. If it was made compulsory these men should have an opportunity to retire.

Sir HENRY CRAIK protested against the campaign which had been carried on against the inoculation of troops. Inoculation was carried out in the general interest of the health of the troops.

Dr. C. ADDISON (Parliamentary Secretary to the Board of Education) said that he had been asked by the Under Secretary for War to deal with the question of inoculation. Was this thing desirable in itself? Would it prevent the occurrence of typhoid fever amongst our troops abroad to a material extent? Would it reduce the strain on our men? That was the big question. Where inoculations were carried out with care the number of cases who did badly was infinitesimal. Even if a man did die in a particularly vulnerable moment, that would not prove that this was not a preventive against typhoid. We had a great force on the continent of Europe, greater than we ever had before, and after six months, including three months of the most atrocious weather imaginable, there had only been 421 cases of the disease. The fact that the figures were so small was a vindication of the policy of inoculation. It seemed strange how the disease had picked out the uninoculated men in a very careful way. The more the records of this remedy of inoculation were examined the better did it appear. It was never contended that there were no men who were inoculated who would not suffer from typhoid. In time the remedy might be so perfected that it might become absolutely perfect. He was not contending that it had proved perfect now. The point was this: Was it so much of a protection that it diminished disease in our troops abroad that it was worth doing? There had been 58,000 cases of enteric in the South African War. Up to the present in this war there had been 421. Whatever this was due to, it had at least happened, and let them continue this happy conjunction of affairs and hope that it would continue to happen. It was said that a good many men might have their consciences hurt by compulsion. Many people, however, had made it their business to go about spreading leaflets. "Is it patriotic to oppose the vaccination and inoculation of our soldiers?" That question was asked at the top of one of these leaflets. And the answer given was "Certainly it is." That was a campaign against antityphoid inoculation, but it was not against personal rights. After all, there might be in different parts of the country excess of enthusiasm on the part of officers who sincerely believed that the troops which they were now commanding would be safer inoculated than not. If an officer was taking a battalion out to the

front, and if he believed that the burden of transport would be less and that the fighting units at the front would remain more intact because the men were inoculated, one could understand a little excessive zeal on his part in getting the men inoculated. He hoped that honourable Members would not allow this grave question to be clouded over by trivialities. Let them look at it as a whole. What the Government were doing was designed to protect our men against this disease in France, and he was sure that every honourable Member would coöperate with the War Office in placing no undue obstacles in the way. Mr. W. LONG thanked the honourable gentleman (Dr. Addison) for the stand he had taken on this important matter. The Opposition would support the Government in taking the strongest measures in securing the health of our troops in France. If the Government had given a pledge to recruits not to make inoculation compulsory, and if they thought a change of policy was required, then the change of policy should be made at once. Any men who thought that they were aggrieved by making inoculation compulsory should be given an opportunity of retiring or of being retained for home defence.

WEDNESDAY, FEB. 10TH.

Inoculation in the British Army.

In the further course of the debate in Committee of Supply on Army Estimates, Mr. TENNANT (Under Secretary for War) said that evidence was accumulating in favour of the inoculation of our troops against typhoid. In the South African War, out of 21,000 deaths, 8000 were from enteric fever. The Indian figures also were significant. In India, where the troops ran great risk of disease, over 90 per cent. of the army were without compulsion inoculated. In pre-inoculation days up to 2000 cases of typhoid used to occur annually in India, whereas in 1912 the number was only 118 and in 1913 only 85. As to making inoculation compulsory for future recruits and allowing those who had enlisted under the supposed guarantee of the War Office liberty to remain in the army for home defence only, he could give no answer. The matter was under consideration, and he hoped to be able to give a definite answer shortly. The question between the honourable Member for Haggerston (Mr. Chancellor) and himself seemed to be not so much one of medical authority as one of discipline. It was said that whilst it was stated that inoculation was voluntary in fact, a soldier desiring to remain uninoculated was met by the commanding officers of certain units with a form of compulsion which it was almost impossible to resist. It would be almost impossible to persuade the honourable Member that these commanding officers had acted with the best possible motives, believing that the course adopted by the individual was likely to be prejudicial to the great bulk of the men under his command. That was really the whole point. These commanding officers had gone beyond any leave which they had from the War Office. He had caused instructions to be issued to all commanding officers to say that action such as the honourable Member (Mr. Chancellor) had brought to his notice was undesirable, and would, he hoped, not be repeated. He (Mr. Tennant) did not disguise that he felt that there was a real danger in men going on leave uninoculated and returning uninoculated, because they might bring infection to a body of troops. Lord Kitchener felt this so strongly that he was about to issue instructions that leave must be sparingly granted to men who declined to be inoculated.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

BIRD, G. A., M.B., B.S., B.Sc. Lond., has been appointed Casualty Officer and Resident Anaesthetist at St. Thomas's Hospital.
BLUNT, A. L., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Surgeon at St. Thomas's Hospital.
BONSER, G. A. G., M.R.C.S., L.R.C.P. Lond., has been appointed Casualty Officer and Resident Anaesthetist at St. Thomas's Hospital.
BURT, W., M.R.C.S., L.R.C.P. Lond., has been appointed Senior Obstetric House Physician at St. Thomas's Hospital.
CRANSTOUN, G., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Physician at St. Thomas's Hospital.
DAVIES, J. C., M.B., B.Ch. Oxon., has been appointed Casualty Officer and Resident Anaesthetist at St. Thomas's Hospital.
DOYNE, P. G., M.B., B.C. Oxon., F.R.C.S. Eng., has been appointed Senior Ophthalmic House Surgeon at St. Thomas's Hospital.
ELLWOOD, V. T., M.B., B.Ch. Oxon., has been appointed Junior Obstetric House Physician at St. Thomas's Hospital.
GIMBLETT, C. L., M.B., B.C. Cantab., has been appointed Resident House Surgeon at St. Thomas's Hospital.
GLADSTONE, F. C., M.B., B.Ch. Oxon., has been appointed Resident House Physician at St. Thomas's Hospital.

HEBERT, G. T., M.B., B.Ch. Oxon., has been appointed Casualty Officer and Resident Anaesthetist at St. Thomas's Hospital.
HUNTER, ANDREW, M.B., Ch.B. Edin., has been appointed to the Chair of Pathological Chemistry in the University of Toronto.
JONES, C. O. H., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Physician at St. Thomas's Hospital.
KENNEDY, F. J. M., L.R.C.P. & S. Irel., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Mountrath District of Queen's County.
MACKENZIE, T. C., M.B., Ch.B. Glasg., has been appointed Assistant Medical Superintendent of the Bury and District Joint Hospital.
MCMILLAN, K. H., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Surgeon at St. Thomas's Hospital.
MARSHALL, W. H., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at St. Thomas's Hospital.
MILES, S. H., M.R.C.S., L.R.C.P. Lond., has been appointed Junior Ophthalmic House Surgeon at St. Thomas's Hospital.
MILLIGAN, D. S. E., M.R.C.S., L.R.C.P. Lond., has been appointed Casualty Officer and Resident Anaesthetist at St. Thomas's Hospital.
RAINE, R. T., M.R.C.S., L.R.C.P. Lond., has been appointed Casualty Assistant at St. Thomas's Hospital.
ROMANIS, W. H. C., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Surgeon at St. Thomas's Hospital.
SAI, P., M.R.C.S., L.R.C.P. Lond., has been appointed Casualty Officer and Resident Anaesthetist at St. Thomas's Hospital.
SHARP, J. E., M.R.C.S., L.R.C.P. Lond., has been appointed Resident House Physician at St. Thomas's Hospital.
SHELLEY, L. W., M.R.C.S., L.R.C.P. Lond., has been appointed Casualty Officer and Resident Anaesthetist at St. Thomas's Hospital.
SPARROW, J. A. G., M.B., B.Ch. Oxon., has been appointed Casualty Officer and Resident Anaesthetist at St. Thomas's Hospital.
STIELL, W. F., M.R.C.S., L.R.C.P. Lond., has been appointed Casualty Assistant at St. Thomas's Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ASHTON-UNDER-LYNE DISTRICT INFIRMARY AND CHILDREN'S HOSPITAL.—Senior House Surgeon. Salary £140 per annum, with board, residence, washing, &c.
BARROW-IN-FURNESS, NORTH LONSDALE HOSPITAL.—House Surgeon. Salary £150 per annum, with residence, board, and laundry.
BEDFORD COUNTY HOSPITAL.—Temporary House Surgeon.
BENEDEN, KENT, NATIONAL SANATORIUM.—Medical Superintendent. Salary £350 per annum, with house.
BIRKENHEAD AND WIRRAL CHILDREN'S HOSPITAL, Woodchurch-road.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.
BIRKENHEAD BOROUGH HOSPITAL.—Senior House Surgeon. Salary £120 per annum, with board and laundry.
BIRMINGHAM CITY MENTAL HOSPITAL, Rubery-hill.—Female Junior Assistant Medical Officer. Salary £200 per annum, with apartments, board, laundry, &c.
BIRMINGHAM GENERAL DISPENSARY.—Resident Medical Officer, unmarried. Salary £240 per annum, with apartments, fire, lights, and attendance.
BLACKBURN AND EAST LANCASHIRE ROYAL INFIRMARY.—House Surgeons, Senior and Junior. Salaries £150 and £130 per annum, with board, residence, and laundry.
BOURNEMOUTH, ROYAL NATIONAL SANATORIUM FOR CONSUMPTION AND DISEASES OF THE CHEST.—Resident Medical Officer. Salary £300 per annum, with board, residence, and laundry.
BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £120 per annum, with board, residence, and laundry.
BRADFORD CITY.—Two positions on Staff of Medical Officer of Health in connexion with scheme of Child Welfare. Salary £350 per annum.
BRIGHTON, ROYAL SUSSEX COUNTY HOSPITAL.—House Physician. Salary £100 per annum, with apartments, board, and laundry. Also Junior House Surgeon and Assistant House Surgeon with charge of beds. Salaries £80 per annum, with apartments, board, and laundry.
BRISTOL EYE HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.
BRISTOL GENERAL HOSPITAL.—Senior House Surgeon. Salary at rate of £200 per annum, with board, residence, &c.
BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—Female House Physician. Salary £100 per annum, with board, rooms, attendance, and laundry.
BRISTOL ROYAL INFIRMARY.—Throat, Nose, and Ear House Surgeon. Salary at rate of £120 per annum, with board, apartments, and laundry.
BURNLEY, VICTORIA HOSPITAL.—House Surgeon. Salary £135 per annum, with residence, board, and washing.
BURY INFIRMARY.—Junior House Surgeon. Salary £150 per annum, with board, residence, and washing.
CANCER HOSPITAL, Fulham-road, S.W.—House Surgeon for six months. Salary £100 per annum.
CANTERBURY, KENT COUNTY ASYLUM, Chatham.—Third Junior Assistant Medical Officer. Salary £250 per annum, with quarters, board, washing, &c.
CARMARTHEN JOINT COUNTIES ASYLUM.—Temporary Second Assistant Medical Officer. Salary at rate of £200 per annum, with board, lodging, washing, &c.
CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd-street, W.C.—House Surgeon. Salary at rate of £50 per annum, with board and residence.
CHESTER, CITY AND COUNTY OF THE CITY OF.—Assistant Medical Officer of Health. Salary £300 per annum.
CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £75 per annum, with board, residence, and washing. Also Resident Medical Officer. Salary £200 per annum, with board, &c.

COLCHESTER, ROYAL EASTERN COUNTIES' INSTITUTION FOR IMBECILES AND THE FEEDLE-MINDED.—Medical Officer. Salary at rate of £200 per annum, with board, apartments, attendance, and washing.

COVENTRY, COVENTRY AND WARWICKSHIRE HOSPITAL.—House Physician. Salary £110 per annum, with rooms, board, washing, and attendance.

DAGENHAM TEMPORARY SANATORIUM, Dagenham, Essex.—Resident Medical Officer, unmarried. Salary at rate of £300 per annum, and all found.

DERBYSHIRE COUNTY COUNCIL.—Tuberculosis Dispensary Officers. Salary £400 per annum.

DEVIZES, WILTS COUNTY ASYLUM.—Assistant Medical Officer. Salary £250 per annum, with apartments, board, attendance, and laundry.

DEVONPORT, ROYAL ALBERT HOSPITAL.—House Surgeon, unmarried. Salary £150 per annum, with board and laundry.

DUDLEY, GUEST HOSPITAL.—Senior Resident Medical Officer. Also Assistant House Surgeon for six months. Salary £150 and £120 per annum respectively, with board, residence, attendance, and washing.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—Female Resident House Surgeon. Salary £100 per annum.

ECCLLES AND PATRICROFT HOSPITAL.—House Surgeon, unmarried. Salary £70 per annum, with board, lodging, and washing.

EXETER, ROYAL DEVON AND EXETER HOSPITAL.—Senior House Surgeon for 12 months. Also House Physician and Assistant House Surgeon for six months. Salary at rate of £250 per annum for senior post and £150 for junior posts, with board, apartments, and washing.

GLAMORGAN COUNTY COUNCIL.—Medical Officer for Inspection of Children in Public Elementary Schools. Salary at rate of £300 per annum.

GLASGOW, ROYAL SAMARITAN HOSPITAL FOR WOMEN.—Resident Medical Officer. Salary £25 per annum.

GOVERNMENT LYMPH ESTABLISHMENT, Colindale-avenue, Hendon, N.W.—Temporary Assistant Bacteriologist. Salary at rate of £300 per annum.

HALIFAX ROYAL INFIRMARY.—Second and Third House Surgeons, unmarried. Salary £120 and £100 per annum respectively, with residence, board, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Assistant Casualty Medical Officer, unmarried, for six months. Salary £30, with board, residence, &c.

HULL, VICTORIA CHILDREN'S HOSPITAL, Park-street.—House Surgeon and Assistant House Surgeon. Salary £60 and £50 per annum respectively, with board and laundry.

KENSINGTON TUBERCULOSIS DISPENSARY, 119, Ladbroke-grove, W.—Temporary Medical Officer. Salary at rate of £500 per annum.

LABORATORIES OF PATHOLOGY AND PUBLIC HEALTH.—Bacteriologist. Salary £170 per annum.

LINDSEY (LINCOLNSHIRE) COUNTY COUNCIL.—Combined Temporary Assistant Tuberculosis and Assistant School Medical Officers. Salary at rate of £300 per annum.

LIVERPOOL INFIRMARY FOR CHILDREN.—Two Resident House Physicians for six months. Salary £30 each, with board and lodging.

LONDON HOSPITAL, E.—Assistant Surgeon.

MANCHESTER, COUNTY ASYLUM, Prestwich.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, attendance, and washing.

MANCHESTER, MONSALL FEVER HOSPITAL.—Second and Third Medical Assistants. Salary £175 and £150 per annum respectively, with board, lodgings, and washing.

MANCHESTER, VICTORIA MEMORIAL JEWISH HOSPITAL, Cheetham.—Female Resident Medical Officer for six months. Salary at rate of £100 per annum, with rooms, board, and laundry.

METROPOLITAN BOROUGH OF HACKNEY AND STOKES NEWINGTON.—Tuberculosis Officer. Salary at rate of £500 per annum.

MIDDLESEX COUNTY ASYLUM, Napsbury, near St. Albans.—Temporary Assistant Medical Officer. Salary 6 guineas per week, with board, lodging, washing, and attendance.

MILE END OLD TOWN INFIRMARY.—Senior Assistant Medical Officer and Junior Assistant Medical Officer. Salary £200 and £150 per annum respectively, with board, lodging, and washing.

MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Junior House Surgeon for six months. Salary £35 per annum, with board, residence, and laundry.

NEWPORT (MON.), ROYAL GWENT HOSPITAL.—Resident Medical Officer. Salary for first six months at rate of £103 per annum, second six months £125, and third six months £150, with board, residence, and laundry.

NORFOLK EDUCATION COMMITTEE.—Assistant Medical Officer. Salary £300 per annum.

NORTHAMPTON COUNTY ASYLUM.—Second Assistant Medical Officer. Salary £250 per annum, with board, &c.

NOTTINGHAM GENERAL HOSPITAL.—Senior House Physician. Salary £120 per annum, with board, residence, and laundry. Also Assistant House Physician for six months. Salary at rate of £100 per annum, with board, residence, and laundry.

OLDHAM ROYAL INFIRMARY.—Second House Surgeon. Salary at rate of £120 per annum, with board, residence, and laundry.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—House Surgeon. Salary at rate of £30 per annum, with board, residence, and washing.

PADDINGTON INFIRMARY 285, Harrow-road, Paddington, W.—Two Assistants to Medical Superintendent of Infirmary and Medical Officer of Workhouse for six months. Salary at rate of £250 per annum, with board, lodging, and washing.

PAISLEY, ROYAL ALEXANDRA INFIRMARY.—Resident House Physician.

PRESTON ROYAL INFIRMARY.—Assistant Resident Medical and Surgical Officer. Salary £120 per annum, with board, residence, and laundry.

PORTSMOUTH ROYAL HOSPITAL.—House Surgeon for six months. Salary £150 per annum, with board, &c.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Assistant Surgeon.

RHONDDA URBAN DISTRICT COUNCIL.—Temporary Assistant Medical Officer of Health and School Medical Officer. Salary at rate of £300 per annum.

ROYAL ARMY MEDICAL CORPS (TERRITORIALS), THIRD 1ST HOME COUNTIES FIELD AMBULANCE (Maidstone).—Seven Medical Men as Officers.

ROYAL DENTAL HOSPITAL OF LONDON, Leicester-square.—Joint Afternoon House Anesthetist. Salary £24 per annum.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, S.E.—Second Resident Medical Officer. Salary at rate of £100 per annum, with board and washing. Also Temporary Honorary Assistant Physician to Out-patients.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, M.—Junior Resident Medical Officer. Salary at rate of £90 per annum, with board, residence, and laundry.

ST. MARY ISLINGTON INFIRMARY, Highgate Hill, N.—Junior Assistant Medical Officer. Salary £140 per annum, with board, residence, &c.

ST. PETER'S HOSPITAL FOR STONE, &c., Henrietta-street, Covent Garden, W.C.—Junior House Surgeon for six months. Salary at rate of £75 per annum, with board, lodging, and washing.

SALFORD COUNTY BOROUGH.—Assistant Tuberculosis Officer. Salary £350 per annum.

SALFORD ROYAL HOSPITAL.—Casualty House Surgeon. Salary at rate of £100 per annum, with board and residence.

SALISBURY GENERAL INFIRMARY.—House Surgeon and Assistant House Surgeon, unmarried. Salary £100 and £75 per annum respectively, with apartments, board, lodging, and washing.

SHEFFIELD CHILDREN'S HOSPITAL.—House Surgeon. Salary £150 per annum, with board and residence.

SHEFFIELD CITY HOSPITALS FOR INFECTIOUS DISEASES AND TUBERCULOSIS.—First Assistant Medical Officer, Second Assistant Medical Officer, and Third Assistant Medical Officer. Salary £250, £225, and £200 per annum respectively, with apartments, rations, laundry, and attendance.

SHEFFIELD ROYAL HOSPITAL.—Female Assistant House Surgeon and Assistant House Physician. Salary £85 and £80 per annum respectively, with board, residence, and washing.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Junior House Surgeon for six months. Salary at rate of £120 per annum, with rooms, board, and washing.

SOUTH SHIELDS, INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTON DISPENSARY.—Junior House Surgeon. Salary £115 per annum, with residence, board, and washing.

STOCKPORT INFIRMARY.—Junior House Surgeon. Salary £100 per annum, with board, washing, and residence.

SWANSEA UNION INSTITUTION.—Resident Assistant Medical Officer. Salary £295 per annum.

TAUNTON AND SOMERSET HOSPITAL, Taunton.—Senior House Surgeon. Salary £120 per annum, with board, lodging, and laundry.

TRURO, ROYAL CORNWALL INFIRMARY.—House Surgeon, unmarried. Salary £150 per annum, with rooms, board, and washing.

TUNBRIDGE WELLS GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, residence, &c.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Physician for six months. Salary £40, with board and lodging.

WAKEFIELD, CITY OF.—Temporary Assistant Medical Officer of Health. Salary £300 per annum.

WALSALL AND DISTRICT HOSPITAL.—Assistant House Surgeon and Anesthetist. Salary £110 per annum, with board, residence, and laundry.

Births, Marriages, and Deaths.

BIRTHS.

BIDWELL.—On Feb. 4th, at Worthing-road, Southsea, the wife of Fleet-Surgeon Lawrence Bidwell, R.N., of a son.

HAYDEN.—On Feb. 4th, at Wymering-mansions, W., the wife of Captain A. F. Hayden, M.B., F.R.C.S., I.M.S. (ret.), of a son.

JORDAN.—On Feb. 4th, at 13, Upper Wimpole-street, W., to Dr. and Mrs. Alfred C. Jordan, a son.

MARRIAGES.

CUNNINGHAM—NEAL.—On Feb. 2nd, at St. Augustine's, Highbury New Park, Frederick Hugh Lester Cunningham, M.R.C.S., L.R.C.P., R.N., to Marguerite Isabel, younger daughter of Mr. and Mrs. John Neal.

HILL—TROLLOPE.—On Feb. 6th, at All Saints', Banstead, Lieutenant F. T. Hill, R.A.M.C., to Ruth Madeline, eldest daughter of Howard W. Trollope, of Banstead, Surrey.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

DANGEROUS FADS.

To the Editor of THE LANCET.

SIR,—I was really taken aback at seeing in one of the recent numbers of *Punch* the advertisement of a baseless campaign that is being waged against vaccines in general and antityphoid in particular.

To us who hold England up as an example, it is hard to realise that there should still exist in a civilised country like yours people ignorant enough to publish and sustain the senseless principles contained in the aforesaid advertisement. And what I think makes that calumnious campaign still worse, under the present circumstances, is the anti-patriotic terms in which it is written.

I think it is about time English people woke up against many such dangerous fads as have been taking root during recent years, such as this one, the antivivisection, and even vegetarianism, and the abuse of other diet fads. Let us hope now that there are more serious things to turn one's thoughts to people will give up brooding over such nonsensical stuff.

I am, Sir, yours faithfully,

Oviedo, Feb. 3rd, 1915.

JAMES B. VILIESID.

ANTIFORMIN.

Mr. Walter J. Matthews, of the laboratory department at the Bristol Municipal Tuberculosis Dispensaries, points out that a perfectly efficient substitute for antiformin hitherto supplied from Germany may be made by passing chlorine into 15 per cent. sodium hydrate to nearly saturation. The chlorine may be prepared by adding pure hydrochloric acid to manganese dioxide. To make one litre 1 lb. of pure acid (specific gravity 1.16) and about 6 oz. of manganese dioxide are needed. The manganese dioxide is placed in a large flask and the acid gradually added through a thistle funnel, warming very gently. The chlorine is carried by a delivery tube to the bottom of the soda solution, which is placed in a tall bottle. Enough chlorine has been added when the soda solution acquires the colour of lemonade. The cost of making one litre works out, on Mr. Matthews's estimate, at about 1s. 1d. Antiformin is used in the bacteriological diagnosis of tuberculosis, and its value in this direction has been referred to many times in our columns.

VERMIN IN THE TRENCHES.

To the Editor of THE LANCET.

SIR,—In 1902 or 1903 I read in *Blackwood's Magazine* extracts from the diary of a planter who was wandering alone for several days during the Indian Mutiny. He became infested with pediculi, and after some days of discomfort hit on the idea of shredding a cheroot and steeping it in water. The application of this "tobacco-water" to his body rid him of a nuisance. This might be worth a trial and could, I think, be easily done in the trenches. An ounce of shag soaked in a quart of water for some hours ought to make a fairly strong infusion. One would not expect it to kill the ova, however.

Norman Walker in his "Introduction to Dermatology" writes about pediculi corporis: "Jamieson says that a small bag of sulphur worn round the neck next the skin acts as a practical 'charm.'"

I am, Sir, yours faithfully,

Feb. 6th, 1915.

M.R.C.S. & L.R.C.P.

ATTACHMENTS TO TELEPHONES.

THE following notice in the "London Telephone Directory" may serve as a warning to future inventors, and so prevent fruitless efforts of ingenuity:—"Attention is drawn to the fact that subscribers are being induced to purchase appliances for attachment to telephones on the ground that they improve the service or have some hygienic advantage. As in nearly all cases these attachments have the effect of either damaging the apparatus or impairing its efficiency—in many cases both—subscribers are reminded that under the conditions of their telephone service the use of such appliances or attachments is, in general, prohibited. The sale to the public of certain appliances which have no such prejudicial effect has been sanctioned by the Post Office, and subscribers should, before purchasing any telephone attachments, satisfy themselves that their use has received official sanction. It is the duty of the Post Office engineers to remove any attachments which have not been officially approved."

FEES UNDER THE MENTAL DEFICIENCY ACT.

"DEFICIT" writes: "I shall be obliged if any of your readers can give me an idea as to the fees one should ask as medical officer under the Mental Deficiency Act."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Papers:—Prof. W. A. Bone and others: Gaseous Combustion at High Pressures.—Prof. W. M. Hicks: The Orbits of a Charged Particle Round an Electric and Magnetic Nucleus.—Mr. S. Chapman: The Lunar Diurnal Magnetic Variation and its Change with Lunar Distance (communicated by Sir F. W. Dyson).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

WEDNESDAY.

SECTION OF THE HISTORY OF MEDICINE (Hon. Secretaries—Raymond Crawford, Leonard G. Guthrie): at 5 P.M.

At 4.30 P.M. Sir William Osler will show a collection of Astruc's works, including his *Genesis*.

Dr. J. D. Rolleston: *Lucian and Medicine*. (Part II.)

Sir Alexander Simpson: Jean Astruc.

THURSDAY.

SECTION OF DERMATOLOGY (Hon. Secretaries—S. E. Dore, A. M. H. Gray): at 5 P.M.

Exhibition of Cases (at 4.30 P.M.):

Dr. G. Pernet: (1) Extensive Tertiary Syphilis in a Woman; (2) Extensive Tertiary Syphilis in a Male; (3) Dermatitis Fectitia.

Mr. J. E. R. McDonagh: Notes of a Skin Disease of Probable Protozoal Origin, with slides.

Dr. S. E. Dore: Favus of Glabrous Skin, with microscopical specimen and cultures.

Dr. Knowsley Sibley: Scleroderma.

Dr. Graham Little: (1) Multiple Tumours. (?) Fibro-sarcoma (private patient); (2) Angioma Serpiginosum (?); (3) Erythema ab igne (?).

FRIDAY.

SECTION OF OTOTOLOGY (Hon. Secretaries—W. M. Mollison, E. D. D. Davis): at 5 P.M.

Discussion:

On Tuberculosis of the Auditory Apparatus.

The following will take part in the discussion:—Sir William Milligan, Mr. Lake, Mr. J. S. Fraser, Mr. Hugh E. Jones, Mr. C. E. West.

Specimens (at 4.15 P.M.):

Will be shown by Mr. A. H. Cheate, Mr. J. S. Fraser, Mr. G. J. Jenkins, Mr. Wyatt Wingrave, Mr. E. D. D. Davis, and others.

Mr. W. M. Mollison (9, Upper Brook-street, W.) will be glad to hear from members wishing to show specimens or to take part in the discussion.

SECTION OF ELECTRO-THERAPEUTICS (Hon. Secretaries—S. Gilbert Scott, E. P. Cumberbatch): at 6.30 P.M.

Discussion:

On the Electrical Treatment of Wounds, Sinuses, Frost-bite, and Sprains, considered more particularly in Relation to the Present War.

Exhibition of Skiagrams.

LONDON DERMATOLOGICAL SOCIETY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY.—4.30 P.M., Cases sent for Consultation. Demonstration of Pathological Specimens. Clinical Cases will be shown by Dr. M. Dockrell, Dr. J. L. Bunch, Dr. W. K. Sibley, Dr. E. G. Reeve, Dr. J. L. Phibbs, and Dr. S. Gooding. 5 P.M., Paper:—Dr. W. K. Sibley: The Treatment of Diseases of the Skin and Mucous Membranes with Carbon Dioxide Snow.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.

WEDNESDAY.—8 P.M., Presidential Address:—Prof. G. Sims Woodhead: Some of the Micro-biological Problems of the Present War.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—8.30 P.M., Paper:—Prof. W. J. Simpson: The War and Cholera.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—4 P.M., Hunterian Oration:—Sir W. Watson Cheyne, Bart. (President).

WEDNESDAY.—5 P.M., Hunterian Lecture:—Prof. H. Blakeway: The Operative Treatment of Cleft Palate.

FRIDAY.—5 P.M., Hunterian Lecture:—Prof. F. C. Pybus: Some Infections of the Tonsil.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Gynaecological (Dr. J. B. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1914 were given in THE LANCET of Dec. 26th, 1914.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1914 are now ready. Bound in cloth, gilt lettered, price 16s., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.			TO THE COLONIES AND ABROAD.		
One Year	...	£1 1 0	One Year	...	£1 5 0
Six Months	...	0 12 6	Six Months	...	0 14 0
Three Months	...	0 6 6	Three Months	...	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, Feb. 10th, 1915.

The following magazines, journals, &c., have been received:—

Therapeutic Gazette, American Journal of Orthopedic Surgery, Medical Review, Public Health, Edinburgh Medical Journal, Post-Graduate, Ophthalmology, Archives of Roentgen Ray, Birmingham Medical Review, Canadian Medical Association Journal, Proceedings of the Royal Society of Medicine, School Hygiene, Journal of Tropical Medicine and Hygiene.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 11 A.M., Mr. Souttar: Demonstration of Minor Operations. 12 noon, Lecture:—Mr. Souttar: Abdominal Diagnosis. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 12 noon, Lecture: Dr. G. Stewart: Neurological Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynaecological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. Bernstein: Applied Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 12 noon, Lecture:—Mr. Souttar: Surgical Anatomy of the Abdomen. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

TUESDAY.—3 P.M., Prof. C. S. Sherrington: Muscle in the Service of Nerve. (Lecture V.)

THURSDAY.—3 P.M., Dr. P. C. Mitchell: Zoological Studies: War and Evolution—Struggle of Species. (Lecture II.)

MANCHESTER HOSPITALS POST-GRADUATE CLINICS.

THURSDAY.—ANCOATS HOSPITAL, Mill-street.—4.30 P.M., Medical and Surgical Cases.

For further particulars of the above Lectures, &c., see Advertisement Pages.

Communications, Letters, &c., have been
received from—

An Address

ON

GUNSHOT WOUNDS OF THE HEAD.

*Delivered before the Medical Society of London on
Feb. 8th, 1915.*

By SIR VICTOR HORSLEY, F.R.C.S. ENG.,
F.R.S.,

CAPTAIN, R.A.M.C. (T.F.); CONSULTING SURGEON, UNIVERSITY COLLEGE
HOSPITAL; SURGEON, NATIONAL HOSPITAL FOR PARALYSED
AND EPILEPTIC.

MR. PRESIDENT AND GENTLEMEN,—The subject of gunshot injuries of the head is, of course, an enormously wide one, and it includes not only the important question of how the actual injury to the brain is produced, but the subject can clinically also be profitably discussed from another point of view altogether—namely, causes of death and how to prevent them. I shall speak more in the former direction, and especially because I have not been permitted to see any cases in the present war except a few exceptional instances which happened to be referred to me unofficially.

PHYSICAL EFFECTS PRODUCED BY HIGH-VELOCITY BULLETS.

I made a large number of experiments¹ on this subject over twenty years ago when the 0'303 rifle was introduced into the services, and the results were fully confirmatory of those in part arrived at previously and independently on the Vetterli rifle by Professor Kocher, especially as to the so-called explosive effect of high-velocity projectiles. It occurred to me then that what was required was a registration method. To this end I employed modelling clay, a substance which roughly resembles the tissues in that it contains a considerable percentage of water in its interstices, but differs with advantage in that when disrupted it remains exactly as the explosive force had deformed it, so that all that was necessary was to fill the cavities produced by the bullet with plaster-of-Paris and thereby obtain an absolutely accurate record of the whole effect of the shot.

The method immediately showed several things: first, that the so-called explosive effect was directly proportional (1) to the sectional area of the bullet; (2) to its velocity; (3) to the amount of water present in the substance through which a bullet passes; and (4) that the forces of disruption were at an angle to the axis of the flight of the bullet which I have never been able to determine completely. I have obtained by means of the clay-plaster method further points concerning the ballistics of the projectile which could not be reached in any other way. The most practically important for our present subject are: (1) Where in the course of the bullet most mischief is done, and (2) by what force.

Point of Maximal Disturbance.

The casts show that the maximal disturbance is produced of course as soon as the bullet at its highest velocity is surrounded by the largest mass of wet tissue. In the animal the conditions are governed by other considerations, of which the most important is that the water-holding material is surrounded by an elastic skin, and that the so-called larger aperture of exit necessarily results

from the driving out of the limb or trunk all the fragments of tissue, bone, and particles of fluid to which the velocity of the bullet has been communicated. The larger aperture of exit is a matter therefore of what happens to be struck in the interior of the skin envelope.

Forces Producing the Injury.

These relate to the two movements of a bullet—first, its progression forward, and secondly, its spin around a central axis given to it by the rifling. It is ordinarily assumed that the progression forward movement is the more important, but in my opinion it is not so, although, of course, the amount of injury naturally depends on the length of traverse of the body by the bullet. The most important movement from a pathological point of view, I suggest, is the rotatory spin; and I came to this opinion by observing, to my surprise, that the rotation of the bullet was still visible on the plaster cast even up to the moment when the bullet ceased to penetrate any more.

It is quite clear that under these circumstances the disruption of the tissues must be attributed in the main to the rotating forces of a bullet; and the transverse section of a plaster cast of the cavity made by a bullet fired into wet clay—in which, therefore, there is a maximum disruption due to the water—shows that the particles of fluid are thrown off practically at right angles to the axis of flight. It is interesting to notice also in some of the casts that these disruptive tears have very often a spiral direction antero-posteriorly, the turns of which are of the same length as the spirals of the grooves of the rifle. Sometimes these have also shown an interesting degree of direction backwards, and then the tear is circumferential to the axis of flight, which reminds one very forcibly of the compression waves of air shown in Professor Boys's beautiful photographs of a 0'303 bullet during its flight. It is clear that if the density of the clay varied suddenly, as it does not infrequently, the results would be a fixation in the plaster of the disruption wave quite comparable to that of the more labile fluid air as in Professor Boys's experiment.

Influence of Shape of Bullet.

We must now consider the question how far the shape of a bullet affects the question of degree of destruction. The so-called explosive bullet, or dum-dum, is a soft-nosed lead bullet which deforms very easily, and by its expansion greatly increases the sectional area. Very considerable confusion seems to have arisen recently because the modern jacketed rifle bullet has been made more and more pointed until there is a very great contrast between the long, sharp nose and the flat base. It has actually been supposed that this bullet makes a much worse wound if it advances through the tissues base foremost instead of the apex, whereas, of course, the result being proportional to the sectional area, it makes no difference.

This brings me to the next point, of which a good deal has been made on purely hypothetical grounds—namely, the question of the modern pointed bullet turning over during its passage through the tissues. Undoubtedly turning over of an elongated projectile is a very common event. To find out whether it was more common now with the modern-shaped bullet than with the old conical projectile I asked Mr. Daw, of Messrs. Hollands and Hollands, kindly to make for me some 0'22 calibre cartridges with

¹ Proceedings of the Royal Institution of Great Britain, 1895, vol. xiv., p. 28, No. 4773.

bullets of the same weight as the ordinary conical pattern, but pointed like the modern service projectile, and of course with the same load. This he very kindly did, and I show you the records of experiments made by the clay method under as nearly as possible similar conditions, the first being an imitation service bullet, the second the old conical pattern (both these being 0.22 calibre), and the third the larger 0.310 soft lead bullet to contrast with the service bullet, and to settle again the question of the deformity caused by the various projectiles respectively. This point, I may mention, I had already dealt with in my first experiments 20 years ago, and which, as I have already stated, went to show that the apex of a bullet had no bearing on the immediate question of amount of destruction. I have also dealt with it in a report furnished to Lord Kitchener and published by him.

Turning Over.

Some misconception as regards turning over has arisen, because it seems to be imagined that a very pointed bullet might turn over and over round a transverse axis through the middle of its length, progressing, in fact, like a wheel, but this is not the case, it only turns over once. Turning over is very common, but as is shown when the bullet enters clay or soap it does not happen until nearly half its course has been passed over—i.e., when the progressive velocity is greatly reduced and the advance of the bullet becomes more sensitive to obstructions which will first affect the light tip, the momentum of which is very different to that of the base. Further, in consequence no doubt of the greater obstruction and friction set up when the bullet travels at right angles to its long axis, its traverse of the tissues is much reduced, but the spin due to the rifling continues to the end.

As regards the disturbance of the tissues caused by turning over the net result is conversion of a tubular wound into a cleft which is nearly triangular in cross section, a narrow isosceles triangle, the base of which is caused by the base of the bullet and the apex by the point. When turning over has reached its complete development there is certainly rather more appearance of disruption, but on measuring the circumference of such a cast there is little difference between the "turned over" region with the immediately precursory cylindrical part of the bullet's course. The practical conclusion which follows from these facts is, of course, that turning over is not to be credited, as it has been, with doing much harm, the real cause of great destruction of tissue, &c., being, of course, the high velocity and rapid spin.

Fragments of Bone.

The clay-plaster method showed me another fact that I had not considered fully. It is that the deep penetration of the brain by a fragment of bone is in the first place the simple consequence of the high velocity of the bullet being communicated to such bodies much lighter than itself, and therefore capable of proceeding as far as and even farther than the shot. In view of the fact that any such fragment may be infected, it follows that at the first operation every reasonable search must be made for fragments as they certainly may later cause the death of the patient.

Dr. Bruce's beautiful radiogram is an interesting example because the shrapnel bullet, partly caught

by the edge of the hole, nevertheless has sent on five fragments, one streaked with lead, deeply into the brain. This was the case of an officer who came under my care some ten days after he was wounded at the end of August. There was a foul small round wound above the left frontal eminence which Dr. Spitta found was infected with staphylococcus aureus, and it led into an abscess cavity about 2 inches deep. I removed the purulent debris, fragments, &c., cut away the original wound in skin and bone, and disinfected with sublimate lotion, hydrogen peroxide, and weak carbolic. Vaccination with autogenetic vaccines was carried out by Dr. Spitta for two months. The patient has made an excellent recovery; the cavity has after three months cicatrised, and he has returned fit for light duty. The distance of penetration of the bone fragments in this case is exaggerated, of course, by the retention of the shrapnel bullet on the inner edge of the hole.

CLINICAL FEATURES.

Perhaps the most important subdivision of clinical conditions which are special is that of causes of death.

1. *Concussion.*

Several cases have been reported of fatal concussion without penetration of the skull. These are, of course, perfectly possible because they fall into the same category as the deaths caused by the simple blow of a cricket ball. They are apparently due to direct paralysis of the respiratory and cardiac centres in the bulb. Mr. Walter Spencer and I showed many years ago that mere pressure on the unopen skull, if sufficiently severe on thin parts, could affect the intracranial tension so as to interfere with the functional activities of these centres.

2. *Rise of Intracranial Pressure.*

Duret showed many years ago that the most paralysing effects on the centres of organic life were produced most easily by force applied in what he called the fronto-bulbar axis, and he showed that the effect of shock applied to the frontal region was transmitted largely by the cerebro-spinal fluid to the interior of the ventricles, and even to the fourth ventricle. This is undoubtedly the first effect of a gunshot wound to the head, and evidenced by functional inhibition of the respiratory centre, as Kramer and myself showed first in 1897. Concurrently one has, of course, immediate hæmorrhage and therefore an equal immediate rise of intracranial pressure. If this is not relieved the embarrassed respiratory centre fails. At the same time the vagal centre is at first stimulated and causes very slow beats of heart, and as the pressure rises this gives place to paralysis of the vagal mechanism, and then begins the fatal and final stage. Probably a certain number of deaths in cases of this kind could be saved by immediate operation, and I have under my observation now an officer whose life was so preserved by Major Sherran, R.A.M.C., who, recognising the urgency of this condition just described, operated at the field dressing station within a very few minutes of the infliction of the wound by trephining and washing out the extravasated blood, thus releasing the pressure and saving the patient's life. The patient is now gradually recovering. In many cases if there is a good blood pressure the intracranial tension often prevents a rapid hæmorrhage.

3. Sepsis.

This is, of course, primarily and in the vast majority of cases due to incomplete disinfection of the original wound, but also to the fatal and detestable practice of "leaving head cases alone," which being the outcome of ignorance both of the functions of the brain and of the principles of anti-septic surgery, led many surgeons of the old school (some of whom apparently still survive) to leave a patient steadily to die rather than perform the duty of attempting to save him. I believe this wicked tradition was also in part created by the fact that the leucocytic barrier, whether subdural or intracerebral, was occasionally quite equal to fighting off the infection, and because such a neglected patient got well, the non-comprehending surgeon said, "Let us leave head cases alone as a rule!" It is to the credit of the British Army Medical Service that they showed in their observations and work during the South African War the falsity of this error. We may hope, therefore, that the example of the brilliant surgery of officers like Major Sherran will prevent cases arriving in England under conditions hopeless of restoration both of life and function.

One word in conclusion on general septic infection. Suppose the subdural space is infected and cerebro-spinal meningitis results. Are these cases necessarily fatal? Evidently they are not, as, indeed, Mygind had always contended. What is to be our routine? A case I saw with Dr. Fraser at Southampton, and which I hope he will publish, suggests that the course adopted in that instance might be generally tried—viz., free opening and disinfection by irrigation of the cranial subdural space at the seat of the injury, a liberal lumbar puncture (1½–2 ounces), repeated if improvement arrested, and autogenetic vaccine treatment. I understand that at Cambridge repeated lumbar puncture has been most efficacious in the treatment of the parallel condition of epidemic cerebro-spinal meningitis.

4. Hernia Cerebri.

A great deal of unnecessary importance used to be given to the condition known as hernia cerebri, as its occurrence was proportionate to the septic decomposition which characterised the condition of most of the wounds. In consequence of this latter factor we must divide the subject under the two headings of aseptic and septic hernia.

Aseptic hernia cerebri.—In consequence of the explosive effect of a bullet on the normal brain, if portions of the bones of a skull are carried away, as, for instance, in the formation of a gutter, then the rise of intracranial tension will cause a certain amount of extrusion of the brain substance. This is accompanied by extrusion of the lacerated brain against the edges² of the opening in the skull. Owing to hæmorrhage in the brain substance produced by the explosive effect such a hernia tends to remain only just so long as there is increased intracranial tension, as, for example, in the cases of removal of cerebral tumour, where aseptic herniæ can be studied not infrequently.

Septic hernia cerebri.—I come now to the more difficult question of septic herniæ and their significance. An infection of the bruised brain may

present simply a localised suppurating cavity, in which case there is no hernia. If, however, the leucocytic barrier of the cavity is imperfect and the hemisphere in consequence happens to become the seat of general cerebritis then hernia of necessity follows, and if the mischief spreads the hernia increases because of the spreading infective œdema of the brain. The subdural leucocytic barrier may be quite effective in some cases and yet the hernia increases. This was what one finds referred to very largely in the writings of the old surgeons, and in this case undoubtedly after some time some of the increase is due to the development of granulation tissue in the brain that projects. Such herniæ, if the subdural barrier is good, yields completely to treatment with absolute alcohol and cutting away as the surface rapidly necroses. Various substances have been used for this purpose—e.g., formalin, but for many years I have never found anything better than absolute alcohol.

FUNCTIONAL DISTURBANCE OF THE BRAIN.

The first and most important practical question is how far compensation for loss of functions due to loss of cerebral substance occurs; possibly this is a question which, though attacked by neurologists for 50 years, must remain essentially indeterminate until the function of every part of the brain is accurately ascertained. It will be simplest, perhaps, to consider the matter by two examples—first, a sensory region of the cortex, and secondly, the kinæsthetic. I desire to premise my examples by suggesting that in the human adult there is no evidence of compensation by education or substitution of function in other parts of the brain for function lost by reason of permanent destruction of given areas. Recovery due to absorption of hæmorrhage and re-establishment of partly blocked circulation, however, may be expected to go on for several years if not interrupted by epilepsy and secondary mental change.

(a) Sensory Cortex.

The most specialised centre and most clearly arranged topographically is the visual area. I will, therefore, confine my remarks to that sensory function, and a case that I saw in October last with Dr. Simpson illustrates very well the problem.

The patient, an officer in an infantry regiment, was hit by what was apparently a Mauser bullet on the right side of the head just below the parietal eminence. The bullet passed through the occipito-temporal region, making a deep gutter through the brain and under the skull, emerged through the middle of the right half of the occipital bone, and buried itself in the muscles at the back, where it was extracted by an incision on the field. The patient, who was totally blind, reached London—namely, the 3rd London Base Hospital—on about the fourth day after receiving the wound. Nothing was done to the wound on the head so far as can be ascertained. When I saw him in a nursing home on the seventh day both wounds were inexpressibly foul; the posterior two-thirds of the head was œdematous, the patient who, as before stated, was completely blind, could with difficulty be roused to an order, and his temperature was 101° F.

Under an anæsthetic the apertures in the scalp were explored by a large flap incision, and it was then found that, in addition to the comminution of the skull at the apertures of entry and exit, there was also a line of fracture and comminution about 4½ inches long connecting the holes. Further, the whole lambdoid suture was started so that the occipital bone was loose—i.e., both halves. On clearing away the fracture blood and pus came from underneath the bone, but I considered that the subdural leucocytic barrier had already sealed off much of

² Thus aiding in the formation of the subdural leucocytic barrier, as was first made clear by Schäfer.

the subdural space. The wound was very thoroughly disinfected, irrigated with peroxide of hydrogen and sublimate lotion. As the flap incision was a very free one no further incisions were made in the oedematous skin on the left side of the head. All lacerated portions of brain tissue were removed. Besides pus there were several sloughy and dark pieces of tissue obviously necrosed. The bacteriological inspection of the head wound gave (by Major Embleton) an almost perfectly pure culture of the bacilli of malignant oedema. The patient has made a good recovery so far after frequent dressings with peroxide of hydrogen and weak carbolic lotion.

The immediate question in this case, however, is the recovery of sight. This began to return in the top right-hand corner of both fields, and has now spread until the patient can see probably over most of the upper right quadrant, but he is a good witness. The first recovery of the upper part of the field in this central case interests me because I have shown that in peripheral lesions—i.e., optic neuritis—the pressure is most severe on the upper half of the nerve and disc, and therefore preservation of sight is chiefly in the upper quadrants. (This patient had a remarkable congestion of his discs, but no true swelling.)

My immediate point is that no recovery has taken place in the gravely injured lobe; neither, I fear, can any be expected. As regards the representation of the upper and lower halves of the visual field in the lower and upper parts of the calcarine cortex and the bearing of this further consideration on the present case nothing can justly be said, seeing that the whole occipital suture being started there must have been bruising of some degree, even if slight, affecting the left calcarine region. Mr. Cruise, who has had charge of the case ophthalmologically throughout, will very kindly report on the case.

(b) *Kinæsthetic Cortex.*

The consideration of the loss of function of the Rolandic region is much more difficult, since paralysis of movement is no simple question of the destruction of a so-called motor centre, but also that of a number of sensation conditions and memories.

1. *Loss of movement.*—So far as the loss of motor function alone may be discussed I desire to suggest, from the experience of cases who were wounded in the South African War, that the chief movements of the hand are not restored if the whole arm area of the anterior gyrus has been destroyed.

2. *Loss of kinæsthetic memories.*—The retention of power to move a segment of a limb at all is one thing, but the ability to effect that movement without clumsiness is quite another. This depends on the conservation of what I term the topognostic sense—viz., the relation of a spot touched on the body, to our knowledge and conception of our position in space; and that chiefly in the relation of the spot touched to (a) the distance from the body—i.e., "proximity"; and (b) the distance to the mid-line of the body or "axiality." The loss of the sense of appreciation of these relations and distances is what we call, in popular language, clumsiness, and I have shown that this topognostic sense is represented in both central Rolandic gyri. Further, I believe it is permanently lost if the arm area of both gyri is permanently destroyed. Thus far, therefore, there is no compensation possible by substitution activity of the lower centres. Coarser coördinated movements of shoulder, elbow, wrist, and even of the hand, however, can be furnished by such lower activities.

THE PERNASAL OPERATION FOR FRONTAL SINUS SUPPURATION BY THE ANTERIOR ROUTE.¹

BY P. WATSON-WILLIAMS, M.D. LOND., &C.,

LECTURER ON OTOTOLOGY AND LARYNGOLOGY AT THE UNIVERSITY OF BRISTOL, AND IN CHARGE OF THE EAR, NOSE, AND THROAT DEPARTMENT AT THE BRISTOL ROYAL INFIRMARY; PRESIDENT, BRISTOL MEDICO-CHIRURGICAL SOCIETY.

A FEW years ago the improved technique of operating on the frontal sinuses by the external radical method, and more particularly by the Killian operation, seemed to have solved the question as far as cases of frontal sinus suppuration attended with severe symptoms were concerned. The reported successes left the impression that skill and experience were the only essentials for a good result—that is to say, good in the sense of obtaining a cessation of discharge, headache, &c., though not seldom far from good in the cosmetic result. But these earlier successes have been discounted by several instances of septic osteomyelitis occurring in the practice of those who may justly be regarded as very highly skilful, a complication almost invariably fatal; while numerous instances of very grave deformity from absorption of the "bridge" in the Killian operation, failure to obtain cessation of suppurative discharge and headache, have made every rhinologist pause before advising a radical operation unless the symptoms are so urgent that, notwithstanding these undoubted risks, obliteration of the sinus involved must be advised. And though so far I have escaped the worst of these complications, it is, I fear, more by good fortune than the result of special skill.

Intranasal methods of securing effective drainage by the removal of the anterior end of the middle turbinate body and of the anterior ethmoidal cells around the lower end of the fronto-nasal passage, so as to render lavage of the frontal sinus, by means of a fine 2 mm. cannula, have been practised for many years, and in a large percentage of cases such lavage has proved of undoubted value. But there are many cases where either the sinus cannot be entered and lavaged at all by these methods, or where, if lavage is possible, the passage for the escape of secretions is still so narrow that the drainage is most inefficient and the symptoms unrelieved, so that some improved intranasal operation has long been a desideratum. Schäffer, Spiess, and others managed to open into the frontal sinus floor through the roof of the olfactory fissure, but the results were disappointing, and in the hands of one follower fatal, hence the method was abandoned. To Fletcher Ingals is due the credit of introducing the method of following up the tract of the fronto-nasal duct—that is, entering the frontal sinus outside the middle turbinal and through the natural frontal sinus ostium. All modern methods are developments of Fletcher Ingals's operation—e.g., the operations of Halle, Segura, &c. Unfortunately the operative methods of all these pioneers are open to grave objection on account of their inherent danger, and hence I have endeavoured to devise an intranasal operation which is comparatively safe and certainly in most cases highly efficient.

The fronto-nasal passage, in its downward course from the bony ring of the upper ostium to its lower

¹ Abstract of a demonstration in the Laryngological Section at the annual meeting of the British Medical Association.

FIG. 1.

Bone specimen showing the fronto-nasal passage with probe passing through; the dotted line shows the route of anterior entry through agger and other anteconchal cells. Note the "anterior entry" is well in front of the cribriform plate.

opening in the uncinate groove and infundibulum, is more or less surrounded by anterior ethmoidal cells, and of those that lie in front of this passage we recognise as fairly constant the one or two agger cells below and the usually smaller ethmoidal cells above. All these lie in front of the free margin of the anterior end of the middle turbinal, and for this group I therefore suggest the term "anteconchal cells." By opening up and removing the anteconchal cells we obtain a much more anterior or direct route to the frontal sinus than by endeavouring to locate the more posterior frontal sinus passage at its lower end and following it in its upward and forward direction, the difference between the old posterior and what I call the anterior route being obvious in the specimen. (Fig. 1.) By entering the sinus through the anterior route we keep in front of the cribriform plate, while by retaining the anterior end of the vertical plate of the middle turbinated bone, and restricting the operation to the outer side of this vertical plate, we ensure our being also to the outer side of the cribriform plate, which is the only serious danger zone if we avoid all force in introducing instruments. The operation appears a dangerous procedure unless we bear in mind that the operative field is not only outside, but also in front of the anterior extremity of the cribriform, which was not the case when operating by the old route.

The clinical and also the anatomical conditions to be dealt with largely determine the extent of the operation required. In a large proportion of patients the simple removal of the anterior ethmoidal cells by the anterior route forms a new fronto-nasal passage large enough to admit a No. 17 or No. 19 sound—i.e., the passage is about 6 mm. in diameter, and has therefore about nine times the sectional area of the normal 2 mm. wide passage. This suffices for very free drainage and the patient can usually very soon learn to wash out the sinuses daily.

Such operative measures are restricted to anterior ethmoidal cells, and though undertaken for frontal sinus suppuration they are not extended to the frontal sinus itself in any part. This removal of the anterior ethmoidal cells which obstruct the exit of discharge below the frontal sinus ostium has been the object of the intranasal operations for frontal sinus suppuration for many years, but when attempted in the more or less haphazard way of working from the lower end of the fronto-nasal passage it is a difficult matter to follow up the course of the passage, as one is working from below upwards and forwards in a dangerous area. In 1911 at the annual meeting of the British Medical Association, Mosher, of Boston, demonstrated his method of opening the agger cells from above and so clearing away these anterior ethmoidal cells in a systematic manner. At the same time I demonstrated the method I adopt, which effects the same result from below and without destroying any part of the vertical plate of the ethmoid, a point I think of import inasmuch as it does not involve fracturing through this vertical plate in close proximity to the cribriform plate and laying open venules and lymphatics in this dangerous area to the risk of infection by the purulent discharges from the frontal sinus.

Tilley has adopted Mosher's operation with this difference, that he removes the anterior end of the middle turbinal at the beginning instead of as a final step, and since February, 1914, has used a rasp for assisting in the more complete removal of the agger cells. In the more favourable cases, those in which the frontal sinus ostium is naturally large, being merely obstructed by the diseased ethmoidal cells of the fronto-nasal passage below the sinus ostium, this relatively simple operative measure is very often attended with good result.

FIG. 2.

To show the initial point of entry in the intranasal frontal sinus operation. The small sphenoid-ethmoidal forceps are seen cutting the point of attachment of the middle turbinal to the outer nasal wall, thus entering the fronto-ethmoidal cells

This we may term the incomplete operation. But a "complete" pernasal operation—i.e., an operation not only on the ethmoidal cells but also on the frontal sinus ostium—is called for when, in association with frontal sinusitis, the agger cells and the other anteconchal cells are poorly developed, or the nasal crest projects backward in marked degree. It then becomes necessary to remove the nasal crest by a rasp or burr, sometimes very freely, so as to afford a large entry, measuring 7 or 9 mm. antero-posteriorly by 6 mm. wide, because, after stripping the mucous membrane towards the front and removing the bone, granulations tend to close the passage in the process of healing. Thus, unless the passage is a good deal larger than seems necessary it may contract so much that the operation is ineffectual as a means of obtaining the all-essential permanent free drainage.

Operative Technique.

It is assumed that the extent and depth of the frontal sinuses have been determined by skiagrams prior to operation.

Anæsthesia.—Even the "complete" pernasal operation on the frontal sinus may be done under local anæsthesia, but in the majority of patients a general anæsthetic is desirable, and more especially if operation on the maxillary antrum or sphenoidal sinus is to be done at the same time. Yet, as far as pain is concerned, one may do any of the procedures described for frontal sinus disease under cocaine anæsthesia, using a 20 per cent. solution of cocaine hydrochloride with a little adrenal extract. The patient may be sitting up or lying flat on the back, or slightly inclined; it makes no difference to the ease of operation.

A. Removal of Anteconchal Cells, the "Intranasal" or Incomplete Operation.

1. With the small angular ethmoidal forceps engage the anterior margin of the middle turbinate at its point of attachment to the outer nasal wall.

FIG. 3.

To show the author's small sphenoidal forceps clipping down walls of the ethmoidal cells external to the vertical plate of the middle turbinal.

Cutting through this the forceps enter the anterior ethmoidal cells in front of the fronto-nasal passage (see Fig. 2).

2. Keeping to the outer side of the vertical plate of the ethmoid, clip away all the agger cells and the other anteconchal cells right up to the crista nasalis (Fig. 3).

3. The anterior ethmoidal cells lying behind or above the fronto-nasal duct, including the bulla ethmoidalis, are now removed by the forceps as far back as may be necessary.

FIG. 4.

Skiagram showing the 4 mm. wide guarded electric burr reducing the crista nasalis in a patient.

4. Using the larger forceps, the thicker projecting partitions of the cells are laid open and punched away. Only the blunt tip of the female blade can come in contact with the roof, hence with any reasonable care there is no risk of the roof being perforated.

5. The author's sounds are then passed into the sinus, so as to gauge the size of the fronto-nasal channel thus formed. Often No. 18 or 19 will enter, sometimes 19-23 or 19-25. (The figures give the circumference in millimetres; hence 19 has a diameter of 6.05 mm., or $\frac{1}{4}$ in. A 19-25 sound measures 6 mm. in width and 8 mm. in antero-posterior diameter.)

6. With the small forceps, which now enter freely, the projecting walls of any remaining ethmoidal cells may be clipped away to render the passage more free.

B. The "Pernasal" Frontal Sinus or "Complete" Operation.

7. If a large enough sound will not enter it may be necessary to enlarge the frontal sinus ostium, and to this end the bone corresponding to the nasal crest may be shaved away by the sharp rasp till these large sizes can be introduced or the crest reduced first by the smaller guarded burr. When a No. 10 sound enters the sinus the bony boss can be further burred away with the 4 mm. wide burr until the burr enters the sinus. (Fig. 4.) When the frontal sinus opening lies well to the outer side and tends to guide entering sounds towards the orbital roof, it is well to, unless contraindicated by skiagram, draw the rasp or burr towards the front so as to enlarge the frontal ostium to the front and inwards rather than towards the orbital roof outwards. One is in front of the cribriform

plate here, and there is no danger provided the instrument is really in the sinus.

One advantage that may be claimed for this method of entry as compared with methods with unguarded burrs is that the mucous membrane is not stripped from the posterior and lateral walls of the new passage, for although the cell partitions are clipped away the mucous membrane of the cell bottom is mostly retained. Only anteriorly is the bone laid bare, and that for a strip about 6.5 mm. wide, and this can apparently recover itself by extension from the muco-periosteum on either side. Is it not better to have a 6 or 7 mm. wide passage which is lined with mucous membrane than a wider

discharges disappear. 3. The use of vaccines, &c., has to be considered. But in cases of streptococcal infection it is always safer to give 30 to 50 c.c. of polyvalent antistreptococcic serum immediately before operating, and follow with sensitised vaccines.

If a sufficiently wide fronto-nasal passage to admit a bougie 15 mm. in circumference is obtained without cutting away the thick part of the nasal crest, and the sinus infection is recent, or there is no reason to believe that polypoid degeneration of the mucosal lining has occurred, I do not use a burr or other means for cutting away any part of the floor of the sinus unless subsequent observation seems to render this desirable. (Provided efficient

FIG. 5.

Skiagram showing 6 mm. thick round bougie entering frontal sinus, but carried back so as to impinge against tabula interna because the nasal crest is thick.

FIG. 6.

The same case, but showing the 6 mm. (No. 19, French scale) bougie entering well into the sinus after reduction of the nasal crest by burring.

These two Figures are from the same patient, reproduced actual size direct from the skiagram.

one stripped of mucosa which can only granulate over and which is much more liable to subsequent contraction.

At the conclusion of these procedures the sinus is well lavaged, and finally the anterior end of the middle turbinal may be removed or left for some days, as when it is left intact the channel may become narrowed by subsequent granulations. In many patients I find it unnecessary to remove any portion of the middle turbinal either at the time of operation or subsequently, and in such cases the nasal passage appears to be intact and normal except that a large fronto-nasal passage is found running up to the sinus.

After treatment.—This consists: 1. In lavage of the sinus, first with saline solutions and weak peroxide of hydrogen, and some mild antiseptic, such as colloidal or other silver preparations, iodine solutions, &c., and later with stronger solutions if necessary. 2. In the passage of the largest sound the canal will take comfortably, repeated at short intervals to prevent adhesions, and to ensure the passage remaining widely open until the sinus has become healthier, or the

(drainage is maintained, and the patient has been relieved of pain, headache, and inconvenient discharge, only the lesser operative measures are performed.)

I have entered more than 100 frontal sinuses by this anterior route, doing either the intranasal or the pernasal "complete" operation.

Many have been cured, nearly all have been relieved. But in some few cases it has been necessary to do an external operation subsequently, while in another small percentage it has been impossible for me to reach the sinus pernasally. These exceptional and difficult conditions I propose to discuss in another communication.

Clifton, Bristol.

INFECTIOUS DISEASES IN DUNDEE.—The monthly report of the Dundee Public Health Department shows a marked increase in the number of cases of measles and whooping-cough. Altogether 803 cases were notified during the month of January, and of these 320 were of measles, as against 175 cases the preceding month, and 384 were of whooping-cough, as compared with 132 during December. In January of last year only 324 infectious diseases notifications were made.

LIPÆMIA RETINALIS.

By R. FOSTER MOORE, M.A., B.C. CANTAB.,
F.R.C.S. ENG.,

ASSISTANT SURGEON, ROYAL LONDON OPHTHALMIC HOSPITAL (MOOR-FIELDS); CHIEF ASSISTANT, OPHTHALMIC DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL.

THE earliest accounts of the condition of the blood to which the term lipæmia is applied are by Rollo, of London, in 1798, and Mariet, of Edinburgh, in 1799. The ophthalmoscopic picture which is associated with this condition was first seen and described by Heyl in 1880, since when very few additional cases have been reported. The appearances of the eye fundus are so striking that they cannot be overlooked, and are so characteristic that having once been seen they cannot fail to be recognised, and in addition, so far as I can discover, they form the only means, apart from a blood examination, of diagnosing the condition of lipæmia.

The two cases which form the basis of the present remarks were under the care of Dr. A. E. Garrod, Dr. J. Calvert, and Dr. Morley Fletcher at St. Bartholomew's Hospital, to whom I am indebted for permission to publish them.

CASE 1.—The patient, a man aged 23 years, was admitted under the care of Dr. Calvert on Oct. 2nd, 1914, suffering from diabetes mellitus. He had all the essential symptoms of the disease. His knee-jerks and plantar reflexes were absent, he had lost much flesh, and was a little drowsy on admission. He was of a fresh colour; his fundi were normal. The examination of the urine resulted as follows: Specific gravity 1031; reaction alkaline, phosphates were present. Albumin was present in small amount on one occasion only. Acetone and aceto-acetic acid were present throughout. The quantity passed varied from 7 to 13 pints. The maximum quantity of sugar passed was 266 grammes and the minimum 139 grammes in 24 hours. On Nov. 9th examination with the ophthalmoscope at 11 A.M. revealed the condition of lipæmia retinalis, and the appearances had not changed at 6 P.M. The patient said he was feeling very well, but on inquiry the Sister informed me that he had been drowsy. His colour was fresh and good; it did not strike me as being abnormal. His capillary circulation as tested by pressure on the finger nail was as free as my own. The composition of his alveolar air was examined on three occasions by Dr. George Graham with the following results: Nov. 9th, 7 P.M., 2.56 per cent. CO₂; 10 P.M., 2.2 per cent. Nov. 10th, 9 A.M., 1.0 per cent. On the morning of Nov. 10th air-hunger was very apparent. Ten ounces of blood were withdrawn from the arm by Mr. H. J. Bower and examined by Dr. T. H. G. Shore and Mr. W. H. Hurtley. The patient died in coma at 2.15 P.M. A post-mortem examination was not permitted.

CASE 2.—The patient, a woman aged 25 years, was admitted to John Ward on April 19th, 1905, under the care of Dr. Garrod suffering from diabetes mellitus; she had previously been admitted under Dr. Garrod and also under Dr. Morley Fletcher. Her symptoms were of 15 months' duration. From March to June, 1904, she was under Dr. Garrod's care. At this time she was passing 5 pints of urine, with a specific gravity of 1045, in 24 hours; the amount of sugar was 4.2 per cent., and a strong ferric chloride reaction was present. The eye fundi were normal. On her discharge the amount of urine was reduced to about 50 ounces, sugar was absent, and thirst had disappeared. From Nov. 4th, 1904, to Feb. 8th, 1905, she was under Dr. Morley Fletcher's care. She was now passing from 5 to 8 pints of urine, which contained 5.2 per cent. of sugar, and a strong ferric chloride reaction was again present. She was sent to a convalescent home on Feb. 8th, having gained 9 lb. in weight; her urine still gave a marked iron reaction and contained 4.6 per cent. of sugar. The eye fundi were normal. On April 19th she was readmitted under Dr. Garrod. She was suffering from marked dyspnoea and had vomited. Her breath smelt strongly of acetone. Her knee-jerks and plantar reflexes were absent. The urine had a specific

gravity of 1020, contained much sugar, and showed a well-marked iron reaction. She died in coma 44 hours after admission. Twenty hours before death venesection was performed by Dr. F. A. Hepworth, and a high degree of lipæmia was so discovered. The fundus oculi was now examined, and the striking appearances of lipæmia retinalis were seen. A post-mortem examination was not obtained.

Ophthalmoscopic appearances.—Case 1.—The fundi were examined 27 hours and again 20 hours before death, and the condition of the blood was recognised by this means. The abnormal features were almost entirely limited to the appearance of the retinal vessels. These were of a salmon colour on the disc and for a short distance beyond, but when traced towards the periphery the colour became much less saturated, and gradually merged into a cream colour with almost no pink tinge. The colour of arteries and veins did not differ at all. In the centre of the disc a faint central light streak was seen on the arteries, and by this means, but by no other, could the arteries be distinguished from the veins; towards the periphery both sets of vessels were identical in appearance. Both arteries and veins were well filled, perhaps a little abnormally so, but there was no turgidity or obvious distension. The general tint of the fundus was rather pale. The optic disc was normal in appearance, its edges were perfectly sharp and clear-cut, and there were neither hæmorrhages nor exudates anywhere to be seen.

Case 2.—The foregoing description would apply in every essential particular to this case, but there were two differences of degree. The colour of the vessels was of a more saturated salmon pink and extended further outwards into the peripheral vessels, and all the vessels, whether arteries or veins, were markedly distended and therefore tortuous; they were about twice their normal diameter.

Lipæmia is described as occurring in a number of widely differing diseases—e.g., chronic alcoholism, phthisis, asphyxia, nephritis, phosphorus poisoning, pneumonia, peritonitis, gout, starvation, and diabetes. I have, however, been unable to discover any reported case in which lipæmia retinalis was observed, except where diabetes was the cause.

A description of the appearances seen with the ophthalmoscope is given by the following observers: Heyl,¹ Hale White,² Fraser,³ Futchner,⁴ Heine,⁵ Reiss,⁶ and Turney and Dudgeon.⁷ All were cases of diabetes in young subjects; the oldest was 35, the youngest 17, and the average age was 24. In several of these cases a general pallor of the fundus is described, and in two cases some visual defect, but otherwise in no case is any abnormality described except as regards the appearance of the retinal vessels. The colour of the vessels is the most striking feature, arteries and veins being quite indistinguishable from each other by this means. There is general agreement in describing the largest vessels as being salmon-coloured and the peripheral vessels as being cream-coloured; differences exist only as to the distance towards the periphery to which the salmon-colour extends.

So far as can be judged from the descriptions of reported cases, the intensity and extent of this salmon tint were greatest in the present Case 2; whilst at the other extreme, in Heine's⁵ case the vessels looked as if they contained milk and not blood; in Fraser's³ case the vessels are described as being white; and in Turney and Dudgeon's⁷ report it is stated "the only place where anything approaching a red tint is seen is in the vessels as they come up into the centre of the disc. Before they have crossed the disc this has completely gone, to be replaced by a pale cream colour."

The change of colour of the retinal vessels is so striking that one is tempted to conclude that this implies a chemico-physical change in the hæmoglobin. In no case that I have found has a spectroscopic investigation of the blood been carried out,

and in the absence of any such evidence of change in the blood pigment there are grounds for attributing the altered appearances solely to the opacity of the plasma. Thus the only situation where this change of colour is seen is in the retinal vessels; the general tint of the fundus, which is dependent upon the light reflected from the choroidal vessels, may be a little pale but is not otherwise altered, nor is that of the cheeks. It must be borne in mind that the retinal vessels are peculiar in this, that resting as they do upon the surface of the retina light is reflected direct from their central axial stream without having to traverse any but transparent media. In the case, however, of the normal choroidal vessels the light reflected from them has to traverse a light diffusing medium in the form of the retina with its pigment epithelial layer, and consequently the normal choroidal vessels, as seen with the ophthalmoscope, differ markedly in appearance from normal retinal vessels. When now the central axial stream of the retinal vessels is surrounded by a plasma, which on separating has the appearance of cream, the effect of a ground-glass instead of a transparent envelope is produced.

Much diffusion of the light reflected from the axial stream results from this, and in this particular the condition of normal choroidal vessels is approximated, and consequently the appearance of the two sets of vessels as seen with the ophthalmoscope is very similar. This is seen in three particulars—viz.: 1. The "ground-glass" effect of the opaque plasma does away with the central light streak seen in normal retinal vessels, as a consequence of which the cylindrical contour is lost, and the vessels have the appearance of flat bands or ribbons as is seen in normal choroidal vessels. 2. The colour of the retinal vessels in lipæmia, where the salmon tint is moderately saturated, is almost exactly that of normal choroidal vessels. 3. In both instances there is the difficulty of distinguishing arteries from veins. It is probable, therefore, that the marked change in colour of the retinal vessels is due entirely to the condition of the plasma, and does not imply a change in the blood pigment.

Distension of vessels.—In none of the reported cases are the vessels described as being less well filled than normally, but in several there has been a well-marked degree of distension of them. In Case 2 both arteries and veins were very full and turgid; they were not less than twice their normal diameter, and this was also the case in Heyl's patient; in the remaining cases, however, distension was not conspicuous, the vessels are described as being well filled (Turney and Dudgeon), a little larger than normal (Hale White), rather dilated (Heine), and this last description would apply to Case 1.

Vision.—There may be very marked lipæmia of the retina without any serious interference with vision. In Case 1, 27 hours before death, in reply to an inquiry, the patient said he did not notice any alteration in his sight, he could see about the ward quite well, and could read a newspaper rapidly and without trouble. Turney and Dudgeon say of their patient that "so far as rough tests go her vision may be described as normal," and in Heine's case, though the vessels looked as if they contained milk and not blood, there was "no difficulty with vision." In the cases of Reis and Heyl there was loss of vision; it would seem possible, however, that the defect in these cases was due to

an accompanying retrobulbar neuritis and not necessarily due to the presence of lipæmia. The optic disc is always quite clear, and there is no obvious œdema of the retina, nor are there areas of exudate, and it is a striking fact that retinal hæmorrhages which so readily occur in altered conditions of the blood have never been recorded in lipæmia.

Prognosis.—There is no doubt that lipæmia of such degree as to give rise to the appearances of lipæmia retinalis implies a grave condition, for I have been able to find one case only in which the patient survived after its discovery. It is, however, clear that recovery is possible and that the normal appearance of the fundus may be restored, for Hale White says of his case that "the colour of both sets of vessels became more healthy, and was quite natural after he had been in two months."

Whilst, then, with a general improvement in the patient's condition lipæmia may disappear, there are grounds for surmising that towards the end of the patient's life it may also disappear and constitute an omen of grave import. It has been shown that a large ingestion of fat increases the amount of neutral fats in the blood, and the plasma may be milky from this cause (Schäfer⁸). The fat in the blood in lipæmia, however, is independent of food taken (Naunyn,⁹ Gerhardt¹⁰), and its source would seem to be the reserve stores of body fats, as is the case in the lipæmia of starvation (Hunter²²). If, then, in a case of diabetes the patient should escape coma sufficiently long for his store of body fat to become exhausted, it might well be expected that lipæmia, if previously present, would disappear. Whether in fact this does occur one cannot state; it did not happen in either of the present cases, but in neither was there marked emaciation. It was, however, demonstrated by Boggs and Morris in their experimental lipæmia (*vide infra*), and the cases of Turney and Dudgeon and of Zandy¹⁰ lend some colour to the possibility of its occurrence in man.

Turney and Dudgeon found at the post-mortem examination of their case that "the great omentum had a very remarkable appearance, in that all the fat was gone from it and the tissues had a gelatinous appearance; all the fat round the viscera was similar, and this was well seen in the heart." The subcutaneous fat, although diminished, had not disappeared. Corresponding with this disappearance of the body fat they find that, whereas film preparations of the blood obtained during life showed a very large number of fat droplets of all sizes, similar films of the blood obtained post mortem, prepared by the same method, failed to show the slightest evidence of fat. They were, however, able to show abundance of fine fat granules in the tissue cells. Similar observations were made in Zandy's case.

Turney and Dudgeon suggest that this "disappearance of the fat from the blood in the large vessels is a vital phenomenon conditioned possibly by the febrile state of the last few days of the patient's life"; it would seem, however, that the remarkable manner in which the stores of body fat had become exhausted might supply an explanation of this.

Differential diagnosis.—Heyl in his original paper suggests a certain similarity to leukæmic retinitis. The very characteristic colour of the retinal vessels in lipæmia is entirely absent in leukæmia; this alone would differentiate the two conditions. In addition, however, in leukæmic retinitis the veins are usually greatly more distended than the arteries, especially in the myelogenic variety, and hæmorrhages are always present; these features are

⁸ Gerhardt reports the case of a dog which had spontaneous diabetes; the blood contained 12.3 per cent. of fat, though the animal had had no food for nearly 24 hours.

absent in lipæmia. I do not think that lipæmia retinalis having once been recognised would ever be confused with any other condition.

Experimental lipæmia.—Czerny¹¹ made the following experiment:—

Fat was injected into the jugular vein of a dog, it having been first ascertained that the eye fundi were normal. Forty-eight hours after the injection numerous hæmorrhages were present in the retina, but there is no mention of appearances at all like those of lipæmia. The retinal hæmorrhages in this case were no doubt due to the presence of minute fat emboli, and their method of production was almost certainly precisely similar to that of the retinal hæmorrhages so usually seen in cases of infective endocarditis.

Boggs and Morris¹² produced lipæmia by bleeding rabbits to the extent of 25 c.c. on six days out of seven for a period of some weeks. In from 8 to 16 days, when the red cells had been reduced to about 2,000,000 per c.mm., the serum became milky; when, however, the bleeding was continued over long periods the animal became intensely emaciated, all the coarse body fat disappeared, and the serum lost its milky character. There is no mention of the appearance of the eye fundus in these experiments.

These experiments would seem to lend support to the surmise that should a lipæmic patient survive sufficiently long to become greatly emaciated the lipæmic condition of the blood might disappear.

Boggs and Morris, as a result of their observations, suggest that lipæmia may occur clinically in cases of anæmia, and state that they have seen a moderate degree of it in a case of anæmia secondary to hæmorrhoids. In any case of severe anæmia, pallor of the fundus as of the skin is present, and the retinal vessels, both arteries and veins, have a paler tint than is normal, and show less difference than is usual between the colour of the two sets of vessels. These appearances are, I believe, entirely due to the dilute condition of the blood in such patients. I have examined the fundi of 36 patients admitted to the wards of St. Bartholomew's Hospital suffering from severe secondary anæmia, which was due in most cases to bleeding from gastric or duodenal ulcers.

The average blood count of these 36 patients was 2,506,000 red cells, and the average hæmoglobin percentage was 40; in one case the red cells were so few as 580,000. In most of these the pale colour of the vessels is noted, and in two cases the approximation in colour between arteries and veins is specifically remarked. Retinal hæmorrhages in the vicinity of the disc are so common as to be the rule.

It is worthy of note that in two of these cases Boggs and Morris's experimental conditions were in large measure fulfilled. Both had had bleeding piles for many years, one of them for ten years, and in both severe anæmia had resulted. The blood examinations were as follows:—

Case 1	...	Red blood cells, 2,730,000		Hæmoglobin, 34 per cent.
" 213	...	" " 3,900,000		" 40 "

In the latter of these two cases severe impairment of sight had resulted from the continual loss of blood, and further testimony of the extent to which this slow blood-letting had progressed was evidenced by the degree to which his blood-forming tissues had undergone compensatory hyperplasia; seven weeks after his piles had been ligatured by Mr. R. C. Bailey his red cells had increased to 6,200,000, his hæmoglobin percentage to 105, and his now extraordinarily florid appearance contrasted markedly with his previous bloodless condition.

In neither of these two cases nor in any of the 36 cases mentioned, however, were the appearances of the fundus at all like those seen in lipæmia, nor have I seen anything similar in chlorosis or pernicious anæmia.

No doubt low or moderate degrees of lipæmia may exist without causing visible retinal changes. Normal plasma contains from 0.2 to 0.5 per cent. of fats, either as glycerides or cholesterin esters of the fatty acids, and under certain physiological conditions these amounts may be exceeded without producing retinal changes. Heine believes that the appearances of lipæmia retinalis are only produced when the amount of fat in the blood reaches 4 or 5 per cent.; it may occasionally rise so high as 15–18 per cent. (Umber, F.²⁶)

Conclusions.

Lipæmia retinalis occurs in young diabetics who are usually bordering on coma, and it consequently implies an immediately grave prognosis, but recovery from the condition may occur.

It implies a high degree of lipæmia, and it is probable that in no condition other than diabetes does lipæmia attain a sufficiently high degree to give rise to the appearances of lipæmia retinalis.

Vision may remain unaffected in spite of a very high degree of lipæmia retinalis.

The conspicuous changes in colour and appearance of the retinal vessels are probably entirely dependent upon the opacity of the plasma, and do not indicate a change in the hæmoglobin.

Lipæmia retinalis supplies so striking and characteristic an ophthalmoscopic picture that it cannot be overlooked nor mistaken for any other condition.

Examination of the Blood by Dr. T. H. G. SHORE.

The blood was taken from the median basilic vein, and as it flowed had a noticeably milky or chalky tinge. After a very few minutes the quantity collected in the bleeding bowl showed a whitish layer collecting on the surface. The blood clotted rapidly, and as the serum separated the whitish material separated with it, giving the appearance of blood mixed with milk or cream. Some of the blood was taken straight into a centrifuge tube, and after coagulation had taken place was separated into two layers; the lower, about half the volume of the blood, looked quite normal, but the upper consisted of the milky serum looking after this treatment more than ever like milk. No separation of the constituents of the upper layer could be effected by the centrifuge. The opacity could not be removed by treatment with ordinary quantities of ether, but a slight greasy mark remained on blotting-paper after the evaporation of the ether, showing that some small amount at any rate appeared to be due to an ether-soluble fat. Under the microscope red and white corpuscles were quite normal in appearance. An actual count was not done. Lying free in the serum, both in the fresh blood and in the centrifuge-separated serum, a very large number of minute feebly refractile spots were to be seen, not at all like globules of fat, and no such globules could be seen. These small bodies did not appear to be crystalline, and could not be made to stain with Soudan III. They were not visible in a film stained by Leishman's or Jenner's methods. The presence of intra- or extra-cellular glycogen could not be demonstrated.

Chemical examination by Dr. Hurtley is not yet complete, but an interesting point has been made out in the total absence of β -oxybutyric acid in the blood, although the smell of acetone was very apparent in the breath, the blood, and the urine.

Bentlnck-street, W.

THE OPERATIVE TREATMENT OF BULLET WOUNDS INVOLVING THE VERTEBRAL CANAL AND ASSOCIATED WITH COMPLETE PARALYSIS.

By L. J. J. MUSKENS, M.D.,
AMSTERDAM.

DURING a prolonged visit to Antwerp I had under observation in the various hospitals six cases of lesion of the spinal cord caused by shrapnel or rifle bullets. In the worst two cases of the series where the symptoms suggested complete severance of the cord I advised exploratory operations, and through the kindness of the medical men in charge of the cases (Mr. H. S. Souttar, of the British Field Hospital, and Dr. Bremken, of the Elizabeth Hospital) I was permitted to perform laminectomy. The observations made during and after these operations appear to me to be of some interest, for in each case the cord and dura mater were found intact, although both patients displayed an almost complete loss of all reflexes and complete flaccid paraplegia. These symptoms, I consider, were due to intradural hæmorrhage, while the history of the two cases appears to indicate that operative procedure may be beneficial.

CASE 1.—Patient, aged 28, married, one healthy child. Examined first Sept. 19th, 1914. He was wounded on Sept. 10th, but was unable to say whether by shrapnel or bullet. At the time he was injured he estimated that the enemy were 200 metres distant. When hit he felt a blow and fell down, at the same time losing all sensation in both lower limbs, the right arm, and trunk. He was carried half an hour by comrades, travelled by vehicle for half an hour, then by motor to Aerschot, and from thence to Antwerp by rail. When admitted to the British Field Hospital he was in collapse and saline injections were administered. At this time the pulse was 120, vomiting was persistent, and 60 oz. of urine were removed after his arrival. It was found necessary to catheterise the patient twice daily. On Sept. 17th he was taken down to the X ray laboratory, when severe vesical hæmorrhage occurred and the patient again collapsed; the pulse rose from 90 to 145; temperature was 38.9° C. Digitalis and pituitrin were given, and after six hours he recovered. The urine was at this time strongly alkaline with an ammoniacal odour, while there was a suspicion of pus. The large quantity of blood in the urine made it impossible to examine it accurately. The vesical hæmorrhage was very troublesome for three days, during which time adrenalin washings were used and ergotine was given internally. After this attack the patient improved

somewhat, being able to take nourishment, but incontinence of both urine and faeces continued. The examination of the patient's back showed the point of entrance of the bullet at the level and to the left of the sixth dorsal spine as a brownish wound about the size of a halfpenny with slightly inflamed edges, but little, if any, exudate. At the right shoulder, where the bullet made its exit, the humerus was broken while the whole region was swollen and had a profuse purulent discharge.

The physical examination made on Sept. 19th, 1914, may be taken as presenting a general view of the patient. At this time he was a broad-shouldered, well-built man with a pulse of 90, but weak in character. There was absolute loss of motility and sensibility below a line passing through the upper part of the ensiform cartilage, or about the level of the seventh rib. Immediately above this level the patient complained of continuous pain and irritation over a girdle area. Associated with these distressing symptoms was a feeling of numbness ("as if swollen") also over the same area. Over the whole body below this line the reflexes had almost disappeared. The abdominal and knee reflexes were gone, but a very slight cremasteric reflex was apparently occasionally elicited. The true plantar reflex was absent, but after repeated deep pricking of the sole of the foot a slight flexion of the great toe was observed, evidently as the result of summation of stimuli. It was further noticed that this reaction was better marked if the patient was instructed to make a fist during the application of the stimulus. The Achilles jerk was elicited in a slight degree on both sides when the gastrocnemius was tapped with a metal hammer. The mobility of the hands and fingers appeared normal; any restriction of the movements of the right arm was due to the complicated fracture of the humerus. The abdomen showed marked dermatography. There was no upward movement of the umbilicus when the attempt to sit up was made. There was complete anaesthesia in regard to all forms of sensibility all over the body below the girdle zone of hyperæsthesia already described. Repeated lumbar punctures failed to get any cerebro-spinal fluid. The X ray photographs gave no information as to the nature or character of the deep lesion. On Sept. 20th, 1914, the field hospital not being provided with the necessary apparatus, Dr. Benham (the physician in charge of the case) invited Dr. Sano to come and examine the case with his portable apparatus. Dr. Sano stated that the rapid contraction of the quadriceps elicited on closing the galvanic current was more marked at the negative than at the positive pole. With the faradic current a moderately strong convulsion of the quadriceps was provoked, but if the electrodes were applied over the nerve the contraction was slow and wormlike.

From a general consideration of the symptoms it seemed possible, and even probable, that the lower part of the cord had nervous connexion with the upper, and further, that the symptoms might be caused by particles of bone pressing on the cord. As there was not the slightest sign of spontaneous improvement—on the contrary, a bed sore developed in the right heel, it was decided to do an exploratory laminectomy. The operation was performed on Sept. 24th. At the time of operation the patient was rather weak, pulse rapid and weak, and temperature 39.4°, this rise being the first of that degree during his stay in hospital. The hæmorrhage from the bladder was still present, but Mr. Souttar's urethroscopic examination indicated that it was due probably to vasomotor disturbances. The patient was placed in the prone position usual in kidney operations, and the posterior wall of the vertebral column from the second to the seventh dorsal vertebra removed. The cord so exposed was found to be non-pulsating, and it was necessary to remove a higher vertebral arch so as to expose the normal cord. The dura mater over the non-pulsating part of the cord was exceedingly tense, while the cord appeared to be of about twice its normal volume. The sides of the vertebral column were rapidly examined, but nowhere was any injury to the dura mater found. The condition of the patient necessitated the administration of saline and strychnine, and no time could be spent in attempting to examine the frontal portion of the cord, but the reappearance of pulsation in the cord was taken as proof that the operation had succeeded in relieving pressure. The wound was closed with silk and horsehair sutures. Sept. 26th: The temperature went down at once after the operation, while the distressing girdle pains ceased. Dr. Sano stated that the upper border of

anaesthesia had become lowered some 3 to 4 cm. or to the level of the ninth rib. The knee-jerk was still absent, but the plantar reflex was almost brisk on the right side. Sept. 29th: The anaesthesia had receded to below the costal arch. The right plantar reflex was practically normal, while the left was elicited only after repeated stimulation. I had to leave Antwerp on Sept. 30th, and further notes of the case have not yet reached me, but the patient is said to be in much the same condition (in Ostend, Oct. 10th).

In this case the loss of the deep reflexes would, according to Bastian, have led one to suspect complete rupture of the cord. The slight contraction of the gastrocnemius, elicited by tapping the tendon with the hammer, might have been taken as the result of direct muscular irritation, while the slight plantar reflex might have signified only that the lower part of the cord was intact. The two facts which led us to suspect that the bullet had passed over but had not ruptured the cord were the absence of the complete reaction of degeneration after nine days (Sencert),¹ and that muscular exertion of the left hand (the right arm being injured) tended to increase the slight rest of the plantar reflex. It is evident from the post-operative history that these suspicions were justified, and that no complete rupture of the cord existed.

CASE 2.—Patient, aged 21, wounded Sept. 9th, 1914, at Aerschot. Examined Sept. 26th. A wound made by the entrance of a rifle bullet was found in the left flank at the level of the fifth dorsal spine; the exit of the bullet was at a point 4 cm. to the right of the ninth dorsal spine. When struck the patient fell down and was instantly paralysed. He suffered severely from lancinating pains extending downwards to both knees, and there was incontinence of both urine and faeces. Below the level of the second lumbar segment there was complete loss of motility, while the reflexes were almost completely lost. Irritation of the skin below the scrotum, if continued for 10 to 20 seconds, was followed after an interval of about the same time by a slight contraction of the cremasteric muscle on the same side. With the faradic current both the peroneus and gastrocnemius reacted subnormally; on both sides the kathode make-and-break current resulted in approximately an equal contraction of both muscles. There was a large eschar on the right buttock, which was continually irritated by urine and faeces. Operation for this desperate case was, in consultation with Dr. A. Claus, decided on, and in preparation the eschar and the bullet wounds were treated with tincture of iodine the day preceding the operation. The cord was exposed between the fifth and seventh dorsal spines. The dura mater was exceedingly tense, while the cord was non-pulsating and much increased in volume. The dura mater was quite uninjured. Here again the bullet had passed by the side of the cord. Dr. Bremken and I were, however, able to satisfy ourselves as to the presence of certain splinters of bone which were pressing on the cord. These splinters we were not able to remove completely, but on pressing them back pulsations returned to the cord. It was decided not to open the dura mater because of the risks of infection, and the wound was closed. Sept. 29th: The patient vomited a great deal after the operation, and the temperature went up to 39.6° C., the pulse being 150. The dressing, which was soaked with blood, was removed and replaced by fresh dressing. A little later the temperature fell, and the patient said that a certain degree of "feeling" had returned to his legs. During the first few days of October this patient was forwarded to Ghent. I have not been able to gather any further information about him.

In severe cases of injury to the spine the important question is whether to operate or not. In all other fractures and dislocations the surgeon has a valuable guide in the X ray photograph, but it is of less use for injuries of the back. In fact, each case must be judged on its own merits, and no rule for general guidance can be formulated. We do not refer to neurological symptoms, on which a diagnosis of complete or incomplete rupture of the cord, might be based.

It has of course been definitely shown (Bastian, Bruns) that where the cord is completely severed

the deep reflexes are lost, but the mistake must be avoided of assuming from an absence of reflexes that the cord is completely cut. Sano² long ago urged the necessity for more frequently exploring these cases, but so lately as 1909, in a discussion held by the French Association of Surgery, the general feeling was distinctly adverse to explorative laminectomy because of the uncertainty of diagnosis. Electrical examination is advocated by Sencert³ as an aid in diagnosis; it is certainly helpful, but not infallible.

From my limited experience I venture to draw the following conclusions. 1. The absence of all deep reflexes must not be taken as an absolute proof of complete rupture of the cord. 2. The rapid fluctuation in pressure caused by a passing bullet appears to be sufficient to damage seriously the blood and cerebro-spinal fluid circulation in the cord and to induce complete flaccid paraplegia. It is probable that the pressure exerted by bony splinters is of secondary importance. 3. In cases of paraplegia following on bullet wound to the vertebral column, when there is no recovery of mobility or sensibility ten days after injury, laminectomy appears to be justified. 4. If the opening of the bony canal is not sufficient to restore pulsation in the cord the theca should be opened and the blood clot removed as thoroughly as possible.

It must, however, be pointed out that sanguine hopes of complete recovery should not be entertained. From our experience with caisson paralysis it is evident that the cord is peculiarly liable to damage through variations in pressure. Air bubbles are in such cases formed in the grey matter. It appears quite possible that a bullet passing the intravertebral canal, but leaving the cord itself unhurt, may cause, besides intrathecal hæmorrhage, similar lesions. It will be rarely, if ever, possible to remove the blood clot completely, and further experience must be looked for in order to ascertain whether lasting amelioration in such cases will ensue. Also local serous meningitis may supervene, and in such cases it is highly probable that the patient may benefit from the operation.

A CASE OF ACUTE TETANUS WITH RECOVERY.

(From an Evacuation Hospital, British Expeditionary Force, France.)

BY A. G. WHITEHORNE-COLE, M.R.C.S., L.R.C.P. LOND.,

MAJOR (TEMP.) ROYAL ARMY MEDICAL CORPS, SENIOR STAFF
SURGEON THE ALLIED FORCES BASE HOSPITAL;

AND

W. M. S. ROBINSON, F.R.C.S. EDIN.,

LIEUTENANT (TEMP.), ROYAL ARMY MEDICAL CORPS; JUNIOR SURGEON,
THE ALLIED FORCES BASE HOSPITAL.

THE following is a report of a case of severe acute tetanus with recovery, no prophylactic dose of antitetanic serum having been given.

Private —, wounded on Oct. 22nd, 1914, was admitted to this hospital on Oct. 26th with two shrapnel wounds, one, a large deep ragged septic wound situate on the anterior surface of the right thigh, about the junction of the middle and lower thirds, involving the extensor muscles, and passing upwards and backwards for about 3½ to 4 inches, cone-shaped in character; the other wound, situated on the posterior aspect of the left knee-joint, being about 2 inches by 1 inch in size and quite superficial,

³ XXIIIme. Congrès de Chirurgie, 1909, p. 842.

with a certain amount of inflammation surrounding it. The wounds were thoroughly cleaned up and the damaged tissue removed, irrigated, and dressed with fomentations. For the next few days the large wound was treated with iodine irrigations and boracic fomentations, the latter four-hourly, and the patient was apparently doing well.

On Nov. 1st, at 9.30 A.M., the patient complained of slight stiffness in the jaws and the muscles at the back of the neck, also that the wound in the thigh was "burning" very much. Temperature 99 F. Tetanus was at once suspected, and on inquiry it was ascertained that he had received no injection at the clearing hospital. The wounds did not appear worse; they were cleaning up fairly well. He was given a mixture containing the three bromides, iodide, and nopenhe, four-hourly, and an injection of morphia $\frac{1}{2}$ gr. was administered. In the afternoon he received an injection of 1500 units of antitetanic serum subcutaneously. In the evening the wound in the thigh was causing intense pain and "burning very much"; temperature 100°. He received an injection of morphia gr. $\frac{1}{2}$, and calomel was administered. On the 2nd the morning temperature was 100°. Trismus was very marked, risus sardonicus was obvious, and there were jerking movements all over the body. He received a further injection of 1500 units of antitetanic serum subcutaneously. On the 3rd the temperature was 100°. The patient was removed to a small darkened ward by himself. He now had very marked and violent jerking movements, and arching of the back. The abdomen was retracted and very hard and board-like. He was unable to be fed by the mouth and rectal alimentation was resorted to. On the 4th the patient's condition was about the same. He was given an injection of antitetanic serum intrathecally of 3000 units; chloral hydrate gr. xx. was given four-hourly, and the bromide mixture was discontinued. The injections were administered by Major (temporary) B. Hudson. The wounds were progressing satisfactorily, but were still very painful. Temperature 100°. On the 5th the wounds were less painful and the patient felt better. The jerking movements, especially of the legs, were still marked and the trismus, &c., were still present. On the 6th the temperature was 100°; stiffness of the jaws was relaxing and the jerking movements were less violent. The bromide mixture was resumed. On the 8th the trismus was less marked and the temperature was normal. On the 12th the patient was very cheerful. The jerking movements and the trismus were very slight and the wounds were clean. On the 18th all signs of tetanus had quite disappeared and the patient felt well. On the 22nd he was discharged to hospital ship.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM.—On Feb. 11th Sir Richard Biddulph Martin presided at the annual general meeting of this hospital, and in moving the adoption of the report referred to the improvements which had been made in the nurses' quarters and in the operating theatre. The finance and general work of the hospital were satisfactory. The War Office, he said, had accepted the hospital's offer of 12 beds for the wounded and three of the hospital's five surgeons had volunteered for active service. The seventy-ninth annual report, which was adopted, showed that during 1914 the total number of new out-patients was 1966, as compared with 1854 in 1913, and that the number of in-patients admitted last year was 732, as compared with 641 in the previous year. The number of operations was 686.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Ruptured Unilateral Solid Cancer of Ovary Removed.—Squamous-celled Carcinoma.—Inversion of Uterus.—Exhibition of Specimens.

A MEETING of this section was held on Feb. 4th, Dr. W. S. A. GRIFFITH, the President, being in the chair.

Dr. HERBERT SPENCER read notes of the case of a patient, aged 27, who had a Ruptured Soft, Solid Growth of the Left Ovary, measuring $5\frac{1}{2}$ by $3\frac{1}{2}$ inches, with about a gallon of free blood-stained fluid in the peritoneum. The tumour was removed; the other ovary, appearing healthy, was left behind. The patient subsequently had two children and remained well seven years after the operation. Similar cases were recorded by Hofmeier and von Velits. The tumour had the microscopic characters of a medullary carcinoma. Dr. Spencer did not agree with Pfannenstiel's opinion that in all cases of unilateral papillary tumours, cancer and endothelioma of the ovary, the other ovary should be removed, for he had seen examples of all those conditions remain well seven years after unilateral ovariectomy. He suggested, however, that, notwithstanding its microscopic characters, it was possible that the specimen shown was not malignant.—Dr. CUTHBERT LOCKYER said that he was not convinced from a casual examination of the microscopic section of Dr. Spencer's specimen that it was a carcinoma; he thought it would very likely prove to be an endothelioma, and if that were so the long immunity from recurrence would be more easy to understand, as endothelioma of the ovary was far less malignant than solid carcinoma of that organ.—Dr. HENRY BRIGGS remarked that the tumour shown and admirably described by Dr. Spencer stirred the unsettled problem as to what these tumours really are. As solid adenomata, in the Departmental Museum of the University of Liverpool, Dr. Briggs said he had had them illustrated and catalogued for over 15 years; repeated and recent revisions of the catalogue had left them as they were, awaiting any more acceptable advance in histology.—Dr. AMAND ROUTH asked how Dr. Spencer proposed to decide whether the removed tumour was malignant or benign at the time of operation, and what course he would now pursue as regards the second ovary if he decided that the one removed was carcinomatous?—In reply Dr. SPENCER said he saw no evidence that the tumour was an endothelioma; structurally it was a typical medullary carcinoma, and it did not resemble microscopically the endothelioma he had met with in a dermoid. In reply to Dr. Routh's question, he thought in the case of such a soft tumour as the one shown (which in the fresh state resembled a spleen), it would be difficult to cut satisfactory rapid sections at the time of operation. He had not yet decided whether the tumour was malignant or benign, but had made a suggestion on that point in his paper. A similar case he would treat similarly. If the ovary, apparently normal at the time of operation, grew subsequently, he would remove it, but with very little hope that malignant disease affecting both ovaries would not recur.

Mr. GORDON LEY (for Dr. RUSSELL ANDREWS) read a short communication on Squamous-celled Carcinoma occurring in a Cystic Teratoma of the Ovary.

Dr. R. D. MAXWELL read a short communication on Inversion of the Uterus, (1) Acute, (2) Chronic.—The subject was discussed by the PRESIDENT, Dr. J. P. HEDLEY, Dr. ROUTH, Dr. BRIGGS, Dr. SPENCER, Dr. E. L. HOLLAND, Dr. COMYNS, Dr. BERKELEY, Dr. T. G. STEVENS, and Dr. G. F. BLACKER.

Mr. GORDON LEY demonstrated a Fibroid of the Uterus, showing Invasion by Tubercle.—The specimen was remarked upon by the PRESIDENT, Dr. STEVENS, and Dr. LOCKYER.

The PRESIDENT showed an example of the "Bowel Pack," suggested by Mr. J. L. Aymard, of Johannesburg, in THE LANCET of Jan. 16th, p. 150, which he had made, and found that it answered the purpose well. It is made by coiling fine wire on to a pad of "cellular" cloth, the wire being sewn by a running stitch along its whole length. The wire he used was No. 22 gauge pure tin fuse wire, and was covered in by a single layer of lint sewn on to the pad.

When one of appropriate size is placed in position it keeps the bowels out of the way of the area of operation, and is a valuable improvement on the ordinary pad. It could be bent into any shape without injury.—Remarks followed by Dr. COMYNS BERKELEY, Dr. J. S. FAIRBAIRN, Dr. MAXWELL, and Dr. SPENCER.

CLINICAL SECTION.

Exhibition of Clinical Cases.—So-called Frost-bite.

A MEETING of this section was held on Feb. 12th, Mr. J. CHARTERS SYMONDS, the President, being in the chair.

Dr. JAMES GALLOWAY showed a case of Splenomegalic Anæmia. The patient, a boy aged 8½, had been observed by his mother to have a slight swelling of the abdomen 18 months ago. This enlargement had increased. He was said to have had an attack of jaundice about 15 months ago; his complexion was said to have become paler, and a year ago a severe epistaxis occurred. There had been an eruption of small purpuric spots and an attack of hæmatemesis a few days before he was admitted to hospital in November, 1914. Since that date he had been under constant observation. At first his condition became worse and another attack of hæmatemesis with copious melæna occurred. The lad was pallid and had a slight degree of protrusion of the abdomen; the spleen was markedly enlarged, reaching the level of the umbilicus; the lower edge of the liver could be felt below the costal margin, and this organ apparently extended higher in the abdomen than normal; probably it was enlarged. The blood had been frequently examined and the following report was characteristic. Red blood, fragility normal. Wassermann negative. Rouleaux and fibrin formation fair. Red blood corpuscles, 2,900,000 per c.mm.; hæmoglobin, 30 per cent.; colour index, 0.5; white blood cells, 840 per c.mm.; polymorphonuclear leucocytes, 57.5 per cent.; small lymphocytes, 35.0 per cent.; large lymphocytes, 1.5 per cent.; eosinophiles, 1.5 per cent.; basophiles, 1.0 per cent.; large hyaline, 3.5 per cent. There was no history indicative of syphilis. The father and mother appeared to be healthy. There were three sisters and one brother who were in good health. An uncle on the father's side had hæmatemesis associated with a swollen abdomen, but had recovered his health. An uncle on the mother's side had been treated for hæmatemesis and ascites. The question of removal of the spleen arose.

Mr. H. MORRISTON DAVIES showed the following cases: 1. A case of Mediastinal Teratoma. The patient, a man aged 21, was admitted to hospital in March, 1913. Six weeks previously he had noticed a swelling over the upper part of the left chest, which increased rapidly in size and became red and painful. He was admitted to an infirmary with a temperature of 104.8° F. The swelling was incised through the third space and pus escaped. It was noticed that the pus was of a peculiar consistency. A few days later, as there was no improvement in the patient's condition, another opening was made in the anterior axillary line, portions of the fourth rib being excised. The general condition became worse, and there was expectoration of large quantities of offensive sputum. Some hairs were found in the discharge from the wound, and the condition was recognised as an infected dermoid. He was then transferred to Mr. Davies's care, extremely emaciated, and in a condition of profound toxæmia. His temperature fluctuated between 102° and 104°. The skin around the opening was excoriated, and there was slight bulging of the surrounding chest wall. There was a copious discharge of pus, sebaceous material, and occasionally hairs. The heart was displaced to the right, and cough was accompanied by offensive expectoration. Under local anaesthesia the third left costal cartilage was removed, and the finger-like processes of the teratoma could be seen. A cavity was found extending inwards to the right of the sternum, outwards to the anterior axillary line, downwards to the fourth space, and upwards to under the first cartilages on both sides. A week later, as drainage was inadequate, portions of the third and fourth left ribs were removed under open ether anaesthesia. The patient suffered very greatly from shock, but improved slightly during the succeeding weeks. After two months the left second costal cartilage was removed, the second and third right costal cartilages were divided, and the upper part of the body of the sternum was excised. After another month the teratoma was partially separated from the pericardium.

Two months later further attachments were divided so as to give better drainage. These operations were done under chloroform anaesthesia, and were followed by great shock. The patient improved, and cough and expectoration ceased. Subsequently the projecting portions of the teratoma were on five occasions excised under anaesthesia by gas and oxygen. In June, 1914, Mr. Davies began to separate the main mass of the teratoma from its attachments to the pericardium, aorta, and surrounding structures; it required five operations before the mass was excised. This part of the growth, half of which was exhibited, measured 13 cm. by 8 cm. by 7.2 cm. It contained, in addition to stratified epithelium, hairs, sebaceous matter, mucous follicles, cartilage and bone, cysts containing mucus, and lined by ciliated columnar epithelium. A further portion was treated in the same way and excised in November, 1914; this measured 7 cm. by 5 cm. by 4 cm. Very little of the teratoma remained. The granulations over the pericardium and other structures were becoming rapidly covered with epithelium, and the cavity from which the teratoma was removed had become obliterated to a great extent, partly by the mediastinum and partly by the expansion of the lung. 2. A case of Bronchiectasis treated by Ligation of Branch of Pulmonary Artery. The patient, a youth aged 17, was admitted to hospital in May, 1913. Seven years ago he had a severe attack of bronchitis, from which he never "properly recovered." During the previous year his cough was much worse and he expectorated large quantities of offensive sputum. Physical signs consisted of dulness, weak breath sounds, and coarse râles over the right base. The sputum contained many different forms of organisms, including streptothrices. Early in June the lung was completely displaced by nitrogen, and four days later the right side of the chest was opened through the fourth intercostal space and portions of the fourth and fifth ribs removed. The branch of the pulmonary artery going to the lower lobe was then tied at the root of the lobe. The patient was anaesthetised by infusion of ether and the lung was kept partially expanded by Mr. Davies's hyperatmospheric apparatus. As soon as the chest was opened the vagus was injected immediately above the hilum of the lung with 2 per cent. of novocaine. The patient experienced practically no shock after the operation. The temperature rose on the third day and 24 oz. of clear fluid were aspirated from the right side of the chest. A week later the temperature was still up, and turbid fluid, which contained streptococci, was found in the pleural cavity. This was drained through an opening in the incision. After three days, as the discharge and sputum were now offensive, a counter-opening was made behind through the ninth rib under local anaesthesia. From this time recovery was uneventful. By August the sputum was reduced to about ½ dr. only per diem and a small sinus was present; he was discharged to a home. The patient had since been working for many months. He said that he felt perfectly well and only occasionally coughed (two or three times a week). A skiagram taken at the beginning of last year showed a shadow at the base of the lung, but in one taken this year the shadow had greatly diminished, and the diaphragm was visible for the first time since he came under Mr. Davies's care. 3. A case of Bronchiectasis treated by Rib Mobilisation (Wilm's operation). The patient, a girl aged 15, deaf and dumb, was admitted to hospital in September, 1913, with extensive bronchiectasis involving the whole of the right side. Over the left base the percussion note was impaired; the breath sounds were harsh; expiration was prolonged and there were moist sounds. Nitrogen displacement was tried, but failed, owing to adhesions. Portions of the first nine ribs were removed through a posterior incision. Ten days later the second stage of the operation was done, the first to the seventh costal cartilages, including the costal margin, being cut away. There was slight shock after each operation. The patient's general condition had much improved. The cough and sputum were greatly diminished, and the latter was no longer offensive. The patient, who previously was often drowsy and apathetic, had become a bright girl and able to go out to work for the whole of each day. 4. A case of Osteitis Fibrosa Cystica. The patient, a girl aged 14, fell on her left hip 18 months ago. Pain was slight and passed off in the course of the day. In March, 1914, she again fell on her hip, and since then she had had occasional slight pain and had limped continuously. She

was seen in April, and a skiagram then taken showed a condition of affairs very similar to that which could be seen in one taken this month. There were very slight limitation of flexion, more of extension, some limitation of abduction and adduction, marked limitation of internal rotation, but none of external rotation. The range of movement in this direction was, however, not increased. There was shortening of the limb, and the great trochanter was raised to above Nélaton's line to an extent practically corresponding with the shortening. Thickening at the upper end of the shaft and of the neck of the femur could be felt. The skiagram showed curvature and enlargement of the upper end of the shaft and of the neck of the femur; the bone was expanded and the cystic condition and septa were easily seen. The epiphysis of the great trochanter was unaffected. The only alteration since April was a slight increase in expansion of the outer aspect of the bone.

Mr. STANLEY BOYD exhibited a case, similar to that last shown by Mr. Davies, in a girl aged 12. There was expansion of the upper end of the left femur, and a skiagram showed a central translucent area and also a fissure. There had been pain in the upper part of the femur for which the child had been kept in bed. After going out she had been knocked down by a boy while at play, when the fissure had been produced. At an operation, tissue was removed from within the swelling, which looked like the growing edge of sarcomatous growth, but which microscopically proved to be connective tissue undergoing ossification. Since then the translucency had become almost normal, and the child ran about free from pain or discomfort.

Mr. R. H. JOCELYN SWAN read a short paper on So-called Frost-bite, based on 100 cases among soldiers returned from the front, 80 of whom had been under his care at the Royal Herbert Hospital, Woolwich. The only causal condition common to all was continuous standing with wet feet. There were two distinct groups of cases: (1) Those in which there was little destructive change, but marked subjective symptoms were present; and (2) those in which there was gangrene of various amounts from a superficial skin lesion to that in which one or more toes were destroyed. In the first group there were cutaneous anaesthesia and analgesia. Joint sense and vibration sense might be lost. Patchy hyperaesthesia was sometimes present, and there was pain on movement or pressure. He regarded the condition as resulting from nutritional change and not as a neurosis, which had been suggested by some. With respect to the second group the gangrene was often greatest in the great toe, and the majority were examples of dry gangrene. It was more usual for one foot to be affected, but there was no ready explanation as to why this should be so. The gangrene had no relation to points of pressure. He thought that the condition was attributable to the dependent position of the feet, to wet, and to want of exercise, and not to cold. Canadian officers had told him that the condition was quite unlike that of true frost-bite with which they were familiar. As preventive measures he suggested the wearing of a thin mackintosh covering outside the sock, but inside the puttee, and the free use of vaseline or whale oil to protect against the wet, and that the boots should be large enough to allow of free movement of the toes. The men should be instructed to carry out this movement.—Dr. GALLOWAY likened this condition to thrombotic phlebo-arteritis obliterans.—Dr. E. G. FEARNSIDES said that the cases could be classified into three groups: (1) Those with objective signs with perhaps some sensory loss, but without subjective symptoms; (2) an intermediate group with slight alteration of sensation, showing blunting of sensation, but without anaesthesia, and a band of hyperaesthesia at the upper border of the affected area; and (3) those in which sensation was lost over an area of the stocking type, which in ordinary civil practice would be ascribed to neurosis. In the Balkan War it had been agreed that the objective changes were vascular in origin.

LARYNGOLOGICAL SECTION.

After-treatment of Submucous Resection of the Nasal Septum without Splints.—Exhibition of Cases and Specimens.

A MEETING of this section was held on Feb. 5th, Dr. WILLIAM HILL, the President, being in the chair.

Sir WILLIAM MILLIGAN read a note on the After-treatment of Submucous Resection of the Nasal Septum without Splints. Having used Whitehead's varnish for painting

between the perichondrial flaps and stitches and varnish for the line of incision for several years, he concludes that there is less discomfort and better drainage than after packing the nose. The after-results have been good, and there has been no haemorrhage or haematoma of the septum.—Dr. P. WATSON-WILLIAMS said that packing the nose might cause serious disadvantages, as in cases of sinusitis.—Sir STCLAIR THOMSON agreed, but stated that in simple cases his practice had been to replace the whole of the septum in small pieces and to pack the nose with sponge tissues so that the parts remained in position.

The following cases and specimens were shown:—

Sir WILLIAM MILLIGAN: A woman, aged 30, with Chronic Lymphangitis of the Nose commencing three years earlier.—Dr. WATSON-WILLIAMS had seen similar cases with latent sinusitis.—Mr. H. TILLEY suggested a blood culture for vaccine treatment.—Dr. BROECKART had obtained excellent results by excision of the hypertrophied tissues.

Mr. E. D. DAVIS: 1. A boy, aged 14, from whom he had completely enucleated a large Nasopharyngeal Fibroma with a strong dissector and the finger without splitting the palate under intratracheal ether. 2. Three post-mortem specimens illustrating Diseases of the Pituitary Body treated by Killian-Hirsch operations.—The PRESIDENT referred to the dangers of these operations.—Mr. W. G. HOWARTH said that it was important to distinguish the cases in which the disease was below the sella turcica from interpeduncular and pontine tumours. The latter were generally fatal.

Dr. W. H. KELSON: A man suffering from Laryngeal Obstruction following acquired specific disease. The larynx showed fleshy masses resembling pachydermia.

Mr. W. M. MOLLISON: A patient with Traumatic Fixation of the Right Vocal Cord and Displacement of the Right Arytenoid Cartilage. He had been operated on ten years back for goitre. Such a condition was common after goitre operations; sometimes the lesion was caused by pressure of the thyroid gland and antedated the operation.

Mr. W. STUART-LOW: 1. A man with Dyspnoea caused by Tracheal Compression. Skiagrams of the chest (exhibited) showed a definite shadow, but there was doubt whether this was caused by aneurysm or mediastinal tumour.—Dr. KELSON suggested the possibility of a syphilitic mass. 2. A patient with Epithelioma of the Pharynx and Tongue treated by Diathermy. The glands of the neck had also been punctured with the cautery with marked improvement.

Mr. C. I. GRAHAM: A similar case to the foregoing after operation and dissection of the neck.

Dr. JOBSON HORNE: An Epithelioma of the Tonsil in a woman aged 43.

Mr. H. L. WHALE: A circular piece of tin $1\frac{1}{2}$ inches in diameter, bent and jagged, removed from the gullet of a soldier by oesophagotomy. Recovery was uneventful.

Mr. C. W. M. HOPE, Mr. H. BUCKLAND JONES, and Dr. JOBSON HORNE: Soldiers who had had Gunshot Wounds of the Larynx or Pharynx.

Dr. DAN MCKENZIE: A patient with Synechia of the Nose treated by Diathermy with excellent result.

Mr. TILLEY: Three children of the ages of 7, 8, and 10 years, who had had Acute Suppuration of the Nasal Accessory Sinuses. Complete recovery followed operation in all cases.

Mr. GRAHAM: A patient with Tuberculosis of the Nasal Fossæ, and sections of the tissue containing tubercle bacilli stained *in situ*.

Sir STCLAIR THOMSON produced a report by Professor Shattock on his specimen of Laryngeal Growth, exhibited in December, 1914, stating that the disease was early squamous-cell carcinoma.

Dr. JOBSON HORNE demonstrated microscopical sections of Pachydermia of the Larynx.

MEDICAL SOCIETY OF LONDON.

Discussion on Gunshot Wounds of the Head.

A MEETING of this society was held on Feb. 8th, Sir JOHN BLAND-SUTTON, the President, being in the chair.

Sir VICTOR HORSLEY opened a discussion on Gunshot Wounds of the Head. His paper is published on page 359 of this issue.

Sir DAVID FERRIER said that were it not for the President's express invitation he would not have ventured to take part in the discussion, for he had little or no experience of

the immediate effects of gunshot wounds of the head. He would like, however, to express his high appreciation of the admirable exposition which Sir Victor Horsley had given of the mechanism of this class of injuries. His own experience was limited to the after-effects of gunshot wounds of the head in the form of permanent lesions of different parts of the brain. These did not differ from the effects of lesions caused by disease or other forms of injury, and corresponded in their symptomatology with the position of the lesion according to the recognised principles of cerebral localisation. Thus there might be met with hemiplegia, or monoplegia of different types; aphasia, motor or sensory; affections of vision, hemiopic or quadrantic; as well as a notable absence of either sensory or motor impairment in cases of lesions of the frontal lobes or other so-called "silent" areas. It was astonishing what extensive lesions of the brain were compatible with a fair degree of both mental and physical health. One of the frequent and distressing effects of lesions of the motor area was the liability—apart from the monoplegia or hemiplegia—to Jacksonian epilepsy conditioned, without doubt, by the septic character of the lesion, and the tendency of this epilepsy to persist, even after repeated operations with a view to removal of the irritative focus. Sir Victor Horsley was well acquainted with a case of this kind—an officer wounded in the Boer War, who was still hemiplegic and epileptic after a severe wound of the left motor area, though he had been operated upon on several occasions since that time. In regard to the immediately or rapidly fatal effects of gunshot wounds of the head it was not the result of the cerebral lesion as such (provided it was not in the medulla oblongata), but, as Sir Victor Horsley and Dr. Kramer had shown, of the hydrodynamic effect of the passage of bullets of high velocity through the incompressible semifluid contents of the cranium. This caused compression or compression with effusion, and consequent paralysis of the vital centres of the medulla oblongata. The primary cause of death, as Sir Victor Horsley and Dr. Kramer had shown, was paralysis of the respiratory centre. Cushing was of opinion that the cessation of respiration is secondary to vaso-motor paralysis, but the experiments of Dixon and Halliburton had amply confirmed those of Horsley and Kramer. They had found that when the pressure of the cerebro-spinal fluid is artificially raised by the injection of saline into the subcerebellar cistern, the respiratory centre fails before either the cardiac or vaso-motor centres, and that death occurs unless artificial respiration is kept up. This had an important bearing on treatment. Sir Victor Horsley had pointed out that in certain cases death might be warded off by timely artificial respiration. This, of course, would only be available in cases in which there was no intracranial effusion. But it might be possible that with artificial respiration and free opening of the skull to relieve the intracranial tension, life might be saved. Perhaps some of the surgeons at the front, when they read of the proceedings of that evening, might be induced to resort to such treatment when appropriate occasions arose.

Mr. RICHARD WARREN said that the cases on which his contribution to this discussion was based were met with partly in civil and military practice in England, but more in the service of the Belgian Field Hospital at Furnes, where he had had the opportunity of seeing patients within a few minutes of injury (from bombardment of the town), or within a few hours at the outside (when brought in from the firing line a distance of five or six miles). The subject was therefore being regarded rather from the point of view of immediate results than of the more remote effects, which also formed so important a part of the surgery of the cranium and its contents. The cases met with fell into two groups. Group 1. Injuries of the cranium with little or no effect on the brain. These were for the most part trifling, but might present points of interest as in the following case, which was sent to him by Dr. A. Craster. A Belgian, aged 29, had been struck by a shrapnel ball three weeks before in the right temporal region. There was a small well-healed scar in this region, not obviously inflamed, but the seat of intense pain and agonisingly tender on palpation. The pulse was 80, the temperature slightly subnormal, and no other signs of intracranial trouble were present. A flap was turned down, including the scar; the tissues were found to be matted and stained with lead,

and the pericranium was infiltrated and separated more readily than normally from the skull. Thinking that there might be some inflammatory collection below the skull he trephined, but found the subcranial space and dura normal, nor were there any spicules of bone from a concealed fracture. The scar and thickened periosteum were cut away and the patient made an uninterrupted recovery with complete relief of symptoms. Group 2. Cases where the skull was fractured, whether in the form of a punctured fracture or one widely open and depressed. In most cases of this sort the dura was penetrated and the brain lacerated to a varying degree whereby these military cases differed from a large number of those met with in civil practice in which the dura remained intact and the prospect of infective meningitis was much less. As regards fractures of the skull, puncture fractures were more often the result of bullet or shrapnel wounds, whilst the bursting of common shell was more prone to cause a widely open depressed fracture. Nevertheless, the last result might follow the impact of a bullet, as was shown in the following case. A bullet entered the left orbit in a lateral direction and completely scooped out both eyes, the nasal fossæ, and a good part of the floor of the anterior fossa of the skull, with the result that there was much brain exuding into the widely opened nasopharynx. In spite of the severity of the lesion this patient was doing well six days later, when he had to be evacuated owing to the town being shelled. The main dangers from injuries of this type were primarily from the shattering of, or pressure by effused blood, &c., on some vital part of the brain and later from the onset of meningitis, which was relatively common, since the dura was practically always opened. The widely opened fractures were also dangerous from the effects of contre-coup on parts of the brain other than that immediately concerned in the fracture. It had long been recognised that the anterior part of the brain could be grossly damaged with but little immediate ill-effects, and he had been a good deal struck by the relative well-being of such patients. For example, one patient arrived with a large depressed fracture of the right frontal bone (the result of a shrapnel burst) and a corresponding black eye like an over-ripe tomato, and yet he was quite conscious, calm, and with but little shock. There could be little doubt that when the skull was shattered the force of concussion was thus in many instances broken and the brain as a whole saved from severe and possibly fatal shaking. In other cases of this nature, however, there was widespread pulping of the brain and death was rapid. The danger from meningitis once the dura was opened (as was the rule in these cases) was considerable, both in the punctured and widely open variety; still, a number of cases, even where a large amount of brain had prolapsed, escaped this complication in anything more than a local degree, and the large fungating hernia cerebri ultimately contracted and healed over. As regarded treatment, the main points seemed to be to render the parts affected as aseptic as possible, for which purpose the weak alcoholic solution of iodine was well adapted. The second point was to render the openings in the skull (where the latter was penetrated) sufficiently large to avoid compression, which might follow the swelling of the necessarily inflamed brain, and, at the same time, to remove foreign bodies which might promote sepsis. This was often a simple matter in the case of shell wounds with wide openings, as the loose fragments of skull could be readily picked off and the rough edges of the aperture smoothed with rongeur forceps. The smaller holes caused by bullets were more likely to require an opening with the trephine to afford due access. Another point to be considered was the advisability of searching for bullets, bits of skull, &c. This should be done at once by searching carefully along the track of the penetrating object with a large blunt probe the size of a No. 10 catheter in the case of small wounds caused by bullets, or with the sterile finger in large lacerations. With a large blunt instrument it was not difficult to keep on the track of the foreign body and avoid further injury, whilst the removal of bullets, pieces of skull, &c., would diminish the risk, at a later date, of infective meningitis and encephalitis. Note should, of course, be taken of wounds of exit where the bullet had completely traversed the head, as finding such clues would render prolonged searching for bullets unnecessary. When possible, radiographic assistance was valuable, but under the emergencies of active service it

was often necessary to rely on the large probe or finger. If no bullet could be found after a brief but thorough search one should desist, and later, should the patient survive, accurate estimation should be made by means of radiograms of the position of the bullet or fragment of shell, when, if in an accessible position, it would as a rule be sound policy to attempt its removal. The mortality of the cases with depressed fractures and lacerated brain was undoubtedly heavy, but he could not help being struck with the powers of recovery shown in many instances and regarded with some degree of hope even very extensive injuries of the brain, provided that these affected the more superficial parts of the organ.

Mr. W. H. H. JESSOP called attention to the frequent occurrence of papilloedema after fractures of the vault by bullet and shrapnel, and to the rapid disappearance of it after decompression or trephining. Mr. M. W. B. Oliver had told him that in 30 cases of vault fracture he had observed the condition in 16 cases, and that in every case the ocular signs had disappeared quickly after operation. The swelling of the optic discs was not great, and as a rule there were no hæmorrhages or effusion along the vessels; there was a ring of oedema round the periphery of the swollen disc. The vision was normal or little affected. The early occurrence and complete disappearance of the ocular signs on relief of intracranial pressure pointed to the papilloedema being due to pressure. The term "optic neuritis" ought not to be used for these cases. Two very interesting cases he had seen at No. 1 Base Hospital. One, under Mr. W. D. Harmer, was due to shrapnel wound on the side of the head; the patient was at first completely blind and deaf. After 36 hours the complete blindness was followed by homonymous hemianopsia. The central vision in each eye became normal after operation, and the deafness also was recovered from. The other patient, under Mr. McAdam Eccles and Mr. G. E. Gask, had complete paralysis of the third, fourth, and ophthalmic division of the fifth nerves; the optic disc and vessels were normal, and the vision and fields of vision also normal. The X ray photographs showed six small pieces of shrapnel lying close together near the cavernous sinus. No changes had taken place after six weeks.

Major L. BATHE RAWLING, R.A.M.C.(T.), said that the few remarks which he had to make must necessarily be related to such cases of head injury as were seen after their admission into military hospitals in this country, of men wounded from anything from three days to three weeks previous to admission here. However, so far as he could see, there was less change in surgeons' views as to the correct surgical attitude in this particular branch of surgery than in some others. For example, they had had to alter somewhat their ideas as to fractures of the long bones, more especially in the event of the injury being compound and associated with prolonged suppuration, kept up by the presence of many loose fragments of bone, with perhaps some additional foreign body. Early and extensive operations conducted for the removal of such sources of irritation had not been followed by the success anticipated. Surgery of fractures of the long bones had become rather conservative. With regard to head injuries, however, his experience had been such that he was more than ever convinced that operative interference should be carried out at the earliest possible moment, not necessarily at the field hospital, where conveniences might be wanting, but certainly at the base hospitals in France, and if not there, as soon after their admission into hospital in this country as was possible. Such methods of treatment had been advocated by Bowlby, Makins, Spencer, and others in the South African War, by Lawford Knaggs and himself in this country, and by many others. In his book on the "Surgery of the Skull and Brain," published in 1912, the following statement occurred: "It is accepted that all bullet wounds of the skull and brain call for early operative interference, it being granted that the condition of the patient is compatible with such treatment." In other words, that all cases, unless hopelessly bad, should be operated on as soon as possible. He was convinced that this interpretation was correct, and he could not understand the attitude of those surgeons who advocated and carried out an expectant form of treatment. He had had the opportunity of observing the conditions associated with, and arising from, both varieties of treatment. There was no comparison between the results obtained. The expectant treatment was followed by a much higher rate of

mortality and, in addition, in those patients who recovered without operation, the presence of depressed bone, blood clot in relation to the membranes and brain, and foreign body would certainly assist in the development of those remote effects of head injury which were so well known, of such frequent occurrence, and so difficult to remedy. Consequently, from his general experience of head injuries and from that derived from cases under his care at the 1st London General Hospital, he advocated most strongly early operative interference. This consisted (1) in the treatment of the wound of entry or attempted entry; and (2) in the removal of the foreign body. The presence of a foreign body, whether embedded deeply in the brain or not, might be determined with reasonable certainty by investigating the exact nature of the wound, whether direct, glancing, &c., though, so far as his experience went, the absence of foreign body in the brain was the exception rather than the rule. In all cases, however, X ray pictures should be taken before the operation, stereoscopic if possible. Such pictures would not only show the position of rifle bullets, shrapnel bullets, or casing, &c., but would also afford direct evidence as to the presence and position of depressed and in-driven fragments of bone. The fact that nearly all serious cases of head injury were septic, like so many other wounds that came from the front, merely strengthened his argument for early operation. The prolongation of suppuration was dependent on the presence of these depressed fragments and foreign bodies, and it would continue so long as these were allowed to remain, with the consequent daily threatening of brain abscess, hernia cerebri, and meningitis. So far as actual technique was concerned, the head should be shaved completely—a process that might require the use of several razors, the hair being matted with dirt, sand, and blood. The head should then be washed thoroughly with scrubbing brush and soap, dried, and painted over with iodine. When this had been done the scalp tourniquet should be applied, for it was important that the loss of blood from scalp vessels should be controlled efficiently. The scalp wound should then be enlarged freely in the required directions, the flaps thrown back, their edges touched up with pure carbolic acid, and their under surface with iodine. The condition of the bone could then be investigated. Fractures limited to the external or internal tables were rather more of text-book prominence than of actual occurrence, and it was necessary in practically all cases to trephine or remove loose fragments of bone in such a manner as to expose freely the underlying dura mater and brain. Depressed fragments should be elevated, small loose fragments of bone picked away, and larger fragments treated in a similar manner or thrown back if they retained any direct connexion with scalp or pericranium. In any case it was advisable to obtain a good view of the dura mater, and the surgeon should err on the side of removing too much bone rather than too little. Blood clot, derived from torn meningeal vessels or from the diploic tissue, should be wiped away and bleeding controlled, dural vessels being under-run and diploic foramina blocked with wax. With a dry field, the dura now remained for inspection. If uninjured, the scalp wound might be approximated, with free and efficient drainage. If torn, the dura should be slit up and a careful investigation carried out for fragments of bone or foreign body, all of which might be carried deeply and widely throughout the underlying brain substance. All such loose fragments must be gently picked away, with all respect to the surrounding brain substance. During this procedure a stream of saline solution at a temperature between 110° and 115° F. would help to keep a clean field, washing away blood, brain, débris, &c. The ordinary probe would assist in the detection of such foreign bodies, and the telephone probe in the presence of metallic substances. Personally he had tried the telephone probe on several cases previously to the war, that pattern being utilised which had been invented by Sheen and described in 1905, and which had been improved recently. He must confess, however, that he was not enamoured of the telephone probe; the presence of any foreign body could be detected with the ordinary probe with almost equal facility, and it mattered not whether the foreign body was osseous or metallic—it must be removed. Though of opinion that a considerable area of bone might require to be removed in the investigation of the injury, he thought that one should be much more judicious in the search for the foreign body in the brain. Needless probing

could only do harm, and unless the foreign body was detected with ease it was preferable to wait, further skiagrams being taken to investigate its exact position, and a second operation being performed later. The position of a bullet might demand that the exploration should be carried out over an area distinct from that of the entry of the bullet. Drainage must always be of the most efficient type, even to leaving a considerable area of brain exposed to the surface. No perforating wounds of the skull had come under his care—doubtless due to the fact that they were so frequently fatal in character. The more favourable cases were those in which the osseous and cerebral lesion occupied the frontal and temporo-sphenoidal regions. The more fatal lesions were situated in the posterior half of the skull, especially in the cerebellar region. He would suggest that after the lapse of a few years the society should hold an inquiry into the after-results of these head injuries. There would, he feared, be plenty of material, and he would add that he was sure that the material would be all the more plentiful if operative interference was inadequate or postponed and, more especially, if such methods were not carried out at all.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

The Vaccination Acts.

A MEETING of this section was held on Jan. 8th. Dr. T. P. C. KIRKPATRICK, the President, from the chair, read a paper defining his position with regard to vaccination, and expressing his belief in its efficacy to prevent small-pox in those who were sufficiently often revaccinated. He gave a short synopsis of the history of vaccination in the United Kingdom. In spite of the various Acts, the proportion of the population protected from small-pox by vaccination was steadily diminishing, and showed a tendency to diminish more rapidly in the future. He thought that it would be impossible either to make the compulsory clauses of the Vaccination Acts more stringent or to compel persons to be revaccinated, and under these circumstances vaccination would afford an unreliable protection from outbreaks of small-pox. The experience of Leicester gave hope that such protection might be afforded by good sanitation. Something should be done at once to meet the growing danger of epidemic small-pox.

Dr. NINIAN FALKINER considered vaccination necessary for the protection of the population. Referring to the last Act mentioned in the paper—the Act of 1907—the year 1905 might be taken as the maximum of protection by vaccination in England, Wales, Scotland, and Ireland. At that time the percentage of the population vaccinated in the different countries was: England and Wales, 76 per cent.; Scotland, 85 per cent.; and Ireland, 82 per cent. The figures for the year 1911 (four years after the passing of the Act) were: England and Wales, 52 per cent.; Scotland, 58 per cent.; and Ireland, 73 per cent.; and when the figures for 1913 were available it was expected that a further decline would be shown in the number of those vaccinated. The percentage of conscientious objectors in England and Wales had increased from 8.4 per cent. to 23.4 per cent., and in Scotland from 5.6 per cent. to 24 per cent.

Sir JOHN MOORE referred to the perfunctory enforcement of the Notification Act in Ireland. He looked upon it as a farce. He was quite sure that sanitation would not afford any protection against small-pox in Ireland so long as there were no medical superintendent officers of health except in Dublin, Belfast, Cork, and Londonderry. He quoted Dr. C. K. Millard, whom he looked upon as sitting on the fence—"I am prepared to admit that a universal system of vaccination and revaccination, if effectively carried out, would abolish small-pox." What was wanted, Sir John Moore suggested, was a Minister of Public Health. The Local Government Board in Ireland were complaining that the Vaccination Acts were not being enforced, and instead of getting a mandamus against the guardians whose duty it was to enforce these Acts they approached the corporation of Dublin and pointed out

the necessity of providing extra hospital accommodation for expected cases of small-pox. He suggested that the most practical and effective protection against small-pox was to be found in aseptic primary vaccination, aseptic secondary vaccination, and, of course, sanitation in the fullest sense of the term.

Dr. R. J. ROWLETTE said that Sir John Moore had told them the best methods for preventing small-pox, and he (Dr. Rowlette) was in thorough agreement with him; but the immediate problem was how much of that programme was practical. He considered that the whole programme was not practical. He did not think, nor had Sir John Moore suggested, that revaccination could at present be made compulsory. As to the question of sanitation, he looked upon Ireland as without sanitation. There was only one whole-time medical officer in Ireland. No attempt was made by any section of the community to make sanitation more efficient in Ireland. The community paid certain medical men from £5 to £15 per annum to look after the health of a large district, which showed that the work was not taken seriously; on the other hand, vaccination had been taken seriously, and was fairly well done. Sanitation at the present time was impossible in Ireland, since no one seemed to think it was required, and whatever chance there was of carrying out primary vaccination there was no chance of sanitation.

The PRESIDENT, in reply, said it was now over a century since the medical profession had come to the conclusion that vaccination was the best preventive measure against small-pox. One must, however, consider the evidence. In any other matter it would come as a striking phenomenon to learn that a community which had abandoned a preventive measure found greater immunity than a community that had adopted that measure to the fullest extent. What had to be considered was what was going to be done in Ireland, since primary infant vaccination could not be relied upon and compulsory revaccination could not be got. As long as compulsory vaccination was relied upon the greatest lever which could be got for sanitary reform was lost. He held no brief for antivaccinationists, nor did he agree with them as to the alleged failure of vaccination to prevent small-pox.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held in the Metropolitan Hospital on Feb. 5th, Dr. David Ross, a past President, being in the chair.—Mr. Peter Daniel read a paper on Colitis and its Treatment. Colitis, he said, is a mysterious condition much written about and little understood even by men who see cases post mortem. The name even is confusing, as it implies that the condition is confined to the colon, whereas in cases in which the colon has been removed mucus is still passed. A name describing the condition better would be gastro-enterocolitis. For working purposes a simple classification based on the nature of the discharge answers very well: (1) Colitis, with mucus discharge; and (2) colitis, with all other forms of discharge. Infantile diarrhoea, constipation, and other bowel trouble enter strongly into the causation of mucous colitis, but it is difficult as a rule to obtain a history of such conditions. In about 5 per cent. a history of typhoid fever is obtained. The history of spinal trouble, scarlet fever, sore-throat, diphtheria, whooping-cough, and mumps is also associated, but whether they have any bearing other than as causes of lowered resistance is difficult to say. Oral sepsis plays a strong part in the causation, and it is very rare indeed that a patient with mucous colitis gives a "clean history." In cases of primary (mucous) colitis, if the patient suffers from oral or naso-respiratory sepsis, they almost always develop into the ulcerative or necrotic varieties in consequence of swallowing strepto- and staphylococci. A marked condition in mucous colitis is the thinness and apparent elongation of the intestine, which permits looping and folding and is the effect and not the cause of the disease. The symptoms of colitis are so variable that it is impossible to state them in a small space. There are always pain and abdominal discomfort, and distension, coming on towards night. There is aversion to anything tight about the waist. Hot liquids increase the discomfort and probably cause a disinclination for food and nausea. The pain is unstable and hard to locate, and consequently leads frequently to errors of diagnosis. The only way to arrive at a correct diagnosis is by systematic investigation of the colon

by means of the sigmoidoscope and of the fæces by a pathologist. Physical examination of the abdomen alone is usually negative—often nothing being observed, at times tympanites exists, at others the colon may be felt contracted, especially the sigmoid. The temperature is usually normal or subnormal, and the pulse is slightly altered. The treatment may be medical or surgical. Medical consists of dieting, drugs, massage of the abdomen, and generally carried out over long periods; also hydrotherapy and lavage. Suggestion and suitably dealing with the mental state and despondency. The personality of the physician is a strong factor in the treatment. Castor oil relieves pain, as also does cascara combined with agar-agar; calomel in 1/10th gr. to 1/12th gr. doses two or three times a day is also recommended. If injections are required they should consist of olive oil introduced through a large nozzle carefully, the patient being on the left side at first and later in the genu-pectoral position. Surgical treatment mentioned was short circuiting, which has not proved very successful, appendicostomy for continual lavage, and excision of entire colon. Mr. Daniel spoke in favour of appendicostomy, or in the absence of the appendix of cæcostomy, with the object of perfect lavage. Lotions for this purpose might be normal saline, 5 per cent. glucose as the least irritating, but often chemical lotions must be used for the following reasons. In some cases 1½ or even 2 pints of saline is passed through the appendix; it distends the sigmoid but is not expelled spontaneously; sometimes gentle massage over the colon leads to its expulsion, but this sometimes fails. In some cases an astringent may be necessary; of these the mildest are hazeline, zinc sulphate, a few drops of formalin, or the smallest quantity of silver nitrate, either of which leads to spontaneous evacuation. When the solution is retained it leads to a certain amount of diuresis. As a rule the fluid is rapidly absorbed, but at times the absorption is slower. Mr. Daniel stated that on one occasion he passed the sigmoidoscope while the solution was retained and saw the sigmo-rectal sphincter tightly closed, but a very slight pressure from below relaxed it; then after a small enema of half a pint was used the colonic fluid was usually expelled. Some authorities believe that the non-irritating qualities of olive oil suit the mucosa, but he (Mr. Daniel) found that ol. paraffin liq. placed within the bowel after the saline and bowel contents have passed does more good.

ULSTER MEDICAL SOCIETY.—A meeting of this society was held in the Medical Institute, Belfast, on Feb. 11th. Mr. R. J. Johnstone opened a discussion on Cæsarean Section by reading a very interesting paper giving an analysis of 28 cases of this operation.—Sir Alexander Dempsey, Dr. John Campbell, Dr. G. A. Hicks, Dr. C. G. Lowry, and Dr. Elizabeth Bell took part in the discussion.

SANATORIA FOR TUBERCULOUS POOR IN SWITZERLAND.—Switzerland has during the last 15 years been making strenuous efforts to provide adequate sanatorium accommodation for the tuberculous poor. In 1913 not less than 14 sanatoria with 1084 beds have been built to accommodate and treat 2722 patients, the average duration of the treatment being 132 days. Exact reports referring to 2377 tuberculous patients have just been published in the *Bulletin Sanitaire Suisse*. Of 788 patients in the first stage 97.5 per cent. and of 555 in the second stage 90.5 per cent. were improved, while of 571 patients in the third stage the percentage of improvement reached the number of only 59.7 per cent. It is to be hoped that from year to year fewer patients who have already reached the third stage will be recommended for admittance. 1357 patients, or 57 per cent., became able to resume their usual occupation; 580 (24.4 per cent.) were slightly, and 399 (16.8 per cent.) greatly, hindered in their working capacity. In 41 cases of those in the second and third stage death occurred. The society "Pro juventute" has collected £10,800 to combat the disease. Forty-four ladies' associations disseminated throughout Switzerland have been actively employed in the same service, and have done excellent work, especially in founding and maintaining a score of dispensaries for the tuberculous. The cantons of Lucerne and Grisons have each collected £12,000 to build a sanatorium of their own.

Reviews and Notices of Books.

Text-book of Embryology: Vol. I., Invertebrata.

By E. W. MACBRIDE, M.A., D.Sc., LL.D., F.R.S., Professor of Zoology at the Imperial College of Science and Technology, South Kensington. Edited by WALTER HEAPE, M.A., F.R.S. London: Macmillan and Co., Limited. 1914. Pp. 692. Price 25s. net.

THIS is the first of three volumes intended to deal with the enormous subject of embryology. A second volume will be devoted to that of the lower vertebrata, and a third to that of mammals. In this handsome, well-printed, and superbly illustrated volume on invertebrate embryology the design is to associate the structural development of embryos with broad generalisations of what is known of their physiology—e.g., the correlation between the function of certain organs of a larva and its habits of life, and between function and habit in the course of development. Some results of experimental embryological research are included, while a novel feature is introduced whereby attention is directed to gaps in our knowledge, which indicate promising fields of research as well as the best means of attacking these problems.

The author regards the science of comparative embryology as a gold mine from which rich rewards have already been reaped, but of which only a small part has as yet been developed, and which promises abundance of gratifying surprises and rewarding returns to the worker of the future; but although the labourers are few, the enormous record of facts already disclosed shows that the harvest truly is plentiful, so plentiful indeed that we sincerely trust the editor's hope of stimulating the interest especially of students of medicine will be realised. We doubt, however, whether the average medical student would at once grasp the full significance of a sentence such as this taken at random: "In the oligochaeta the prototroch is never developed at all; the embryo develops into a blastula, which is converted into a gastrula by invagination or by epibole."

An introductory chapter extending to about 30 pages dealing with growth, maturation, and conjunction of germ cells, chromosomes and their bearing on heredity, the recapitulation theory, embryonic and larval phases of development and factors modifying development, is followed by a short account entitled "Practical Hints" as to methods of procedure applicable to all, or nearly all, classes of embryo. Special methods are described with each phylum. Then follow separate accounts of all phyla of the invertebrates from porifera to protochordata. Each phylum is treated with a wealth of descriptive detail and illustrated by means of admirable figures in the text. The 469 illustrations are drawn from many sources—some are original, many are composite, but all are superb and illuminating.

In his "summary" the author arrives at the far-reaching conclusion that in general the larval phase of development represents a former condition of the adults of the stock to which it belongs. This is in substance the recapitulatory theory, the so-called "law of biogenetics," to which the author adds his testimony, and in so doing gives a rational account of recapitulation. "The individual in its development recapitulates the development of the race." An interesting survey of the Lamarckian doctrine leads the author to discuss the part that

may be played by hormones in relation to the theory of inheritance of acquired characters.

In our opinion this work at once takes a place in the foremost rank of embryological studies. It will prove indispensable to all earnest students of zoology. It is dedicated to the memory of his teacher and friend Adam Sedgwick, and is a worthy tribute of a devoted pupil to a beloved and inspiring master.

Manual of Obstetrics.

By EDWARD P. DAVIS, A.M., M.D., Professor of Obstetrics in the Jefferson Medical College, Philadelphia. With 171 illustrations. London and Philadelphia: W. B. Saunders Company. 1914. Pp. 463. Price 10s. 6d. net.

THIS book is dedicated to the students and graduates of the Jefferson Medical College, and is interesting as embodying the teaching of a well-known American obstetrician. It contains a great deal of useful and accurate information on the subject of obstetrics, but there are a number of statements made and methods of treatment described which are hardly in conformity with the teaching on this subject in this country. We are told, for example, that the "placental sound" is usually produced in the large uterine sinuses where the placenta is attached, and that the funic souffle is a hissing, rapid sound, a little slower than the foetal heart and more rapid than the placental sound. The delivery of the crushed head by cranioclasm would mean to the English student the preliminary breaking up and removal of the vault of the skull, but Professor Davis employs the term for the operation of removal of the head by the craniotomy forceps after perforation without previous crushing. The statement that cephalotripsy may be performed upon the unperforated head is not a usual one in modern text-books. The maternal mortality from placenta prævia is more commonly quoted as 5-10 per cent. in most English text-books, rather than the 10-20 per cent. at which it is estimated by the author.

In the section on eclampsia the sentence that "when the resisting power of the patient is greater Nature may endeavour to save her life by producing convulsions" is an odd one, and we are surprised to find that Sellheim's proposal to amputate the breasts for eclampsia is quoted without any condemnation. The statement that when, after the rupture of an ovarian, tubal, cornual, or broad ligament pregnancy, the ovum, having passed upwards into the abdominal cavity, it may engraft itself upon the surrounding omentum, mesentery, peritoneum, or bowel, and gradually develop a placenta and membranes, is misleading and inaccurate. The description of abdominal pregnancy is poor; no attempt is made to distinguish between primary and secondary abdominal pregnancy; nothing is said about the anterior or posterior subperitoneal varieties, and Taylor's important work on this subject is not even referred to. It is difficult to believe that the author would really practise vaginal hysterectomy in the event of a retroverted uterus remaining in the hollow of the sacrum and infection developing after the death of the embryo; why not remove the cause in the shape of the dead and no doubt putrefying embryo?

The legends of some of the figures show a want of care. Thus, "The Foetal Heart Sounds" is the title given to a picture representing auscultation of the pregnant uterus; "The external conjugate by

external pelvimetry," Farabœuf for Farabeuf, and such an expression as "The Infection of the Baccillus Coli Communis," are slips such as one does not expect to find in a book of this kind.

Notwithstanding its defects, however, the book is worth reading as exemplifying the teaching and practice of an American obstetrician.

Butterworth's Workmen's Compensation Cases.

Vol. VII. (New Series). Edited by His Honour Judge RUEGG, K.C., and DOUGLAS KNOCKER, Barrister-at-Law, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond., D.P.H., assisted by EDGAR T. DALE, Barrister-at-Law. London: Butterworth and Co. 1914. Pp. lxxix. + 1011 + 28. Price 12s. 6d. net.

THIS annual volume contains reports of all cases decided from October, 1913, to October, 1914, under the Workmen's Compensation Acts in the House of Lords and Court of Appeal, England, and selected cases from the Irish Court of Appeal and Scotch Court of Session. It constitutes a useful work of reference for the library of a lawyer whose practice is to any considerable extent connected with workmen's compensation, and as the subject so closely concerns medical men it has also considerable interest for them.

Cases of medical interest in which there were appeals during the 12 months dealt with, include *Walsh v. Locke and Co. (Newland), Limited (England)*, in which the old topic of the refusal of a working man to undergo a simple operation in order to regain the capacity to work was under review. In this instance the refusal was that of a miner to have a stiff finger removed, so as to enable him to handle a pick, without a "guarantee of success." The county court judge found the refusal to be reasonable, but the Court of Appeal held that there was no evidence to support that finding. *Jones v. Davies, Limited (England)*, was an appeal concerned with the liability of the workman, unsuccessful in an application to have compensation continued, to pay the fee of a medical man who had examined him for the employers in order to qualify to give evidence. The question was whether the fee was recoverable when the examination had taken place before proceedings were commenced. It was held to be sufficient that a dispute had arisen between the parties. In *Lewis v. Port of London Authority (London)* a good deal of medical evidence, some of it conflicting, had been given, and in the judgment of Lord Justice Pickford the position and the functions of the medical referee sitting as an assessor were discussed and defined, comparison being made with the practice of the Admiralty Court and the amount of weight there given to the advice of the nautical assessors. "He is there," said his lordship, "to give his advice, in the one case upon nautical matters and in the other case upon medical matters. He is not there to give a judgment or to find the facts, and his advice is no part of the judgment, and may be disregarded by the judge, as it has been in the Admiralty Court on not very infrequent occasions."

Naturally, in a large number of cases there is record of accidents involving a considerable amount of medical testimony, although in some of them the consideration of this may not have formed part of the duties of the Court of Appeal. Perhaps the most interesting of these are concerned with the question whether incapacity is due to "an accident" or to "disease," and, again, the variety

seems almost infinite of the ways in which "accidents" may take place, leaving as a matter of dispute whether they arose out of and in the course of the workman's employment. In both these classes of dispute, we need hardly say, medical evidence is very frequently the most conclusive obtainable.

Dairy Chemistry.

By HENRY DROOP RICHMOND, F.I.C. Second edition, revised. With numerous tables and 49 illustrations. London: Charles Griffin and Co., Limited. 1914. Pp. 434. Price 15s. net.

Mr. Richmond's book has always been accepted as a standard work on the chemistry of dairy products, although no new edition has been forthcoming until now, while the first edition was published in 1899. For some years past, however, the author has been seriously handicapped by ill-health. We are glad to learn that this unfortunate reason need no longer deprive all those closely connected with the examination of milk products of the advantage of gaining his more recent experiences on the subject.

In his preface he admits that by lapse of time certain portions of the text had become obsolete, which has necessitated their rejection in the present edition and their replacement by matter based on the latest investigations. We observe that amongst other new matter care has been taken to include the new and improved methods of analysis which have been devised within recent years for the examination of milk and milk products. He has also reserved space for an account of the enzymes in milk and their detection, which, in view of the importance attached to these entities and of their presence indicating raw milk, claim special attention.

The book is a thoroughly practical one, and this revised edition will be heartily welcomed by all those engaged in the control of milk products and in the business of the dairy and milk product factory.

Mutual Aid.

By P. KROPOTKIN. London: William Heinemann. 1915. Pp. 240. Popular edition, price 1s. net.

THIS admirable book was first published in 1902, and is now issued in a popular form on account of its subject matter being a sound reply to the argument of the Bernhardt school of thinkers, who, putting a mistaken construction upon Darwin's principle of the "struggle for existence," maintain that the horrors of the present war are a necessary corollary of that principle. Prince Kropotkin puts forward the thesis—and maintains it by a wealth of facts collected from animal life, savage society, barbarian tribal laws, mediæval society, and modern life—that biological and social progress should be interpreted "not in terms of overbearing brute force and cunning but in terms of mutual coöperation." The result is a work of singular interest, exhibiting very wide reading, written in a simple and clear style, and naturally coloured all through with the candid and transparent personality of the writer.

Few persons besides those who have studied the subject as specialists are aware how deeply the principle of mutual aid sank into, or we may say was the essence of, the life of the mediæval city, and Prince Kropotkin's informing chapters on this subject should be read by everyone. The mediæval guild was the evolutionary product of the tribal "gens" and the village community. It was an

association of men and women working together for the common good of the members, and in this ideal they were at one, as the very name "universitas," the technical and legal word for a guild, shows. There is a remarkable passage in the Psalms which demonstrates how deeply the notion of the connexion between a city and mutual interests had sunk into the minds of men. In Psalm cxxii. 3 the Prayer-book version has, "Jerusalem is built as a city that is at unity in itself." The Vulgate version (the number there is cxxi.) reads, "Civitas cujus participatio ejus in idipsum." The Septuagint reads, πόλις ἥς ἡ μετοχή αὐτῆς ἐπίσταυτό, "a city whose fellowship (sharing) is complete." But the original Hebrew expression means "a city that is well compact together," in reference, probably, to the protecting walls and towers, but without the idea of community or fellowship. After his review of the mediæval city Prince Kropotkin points out how the State tried again and again in various countries to be the only bond of union, and shows how this attempted autocracy broke down owing to the reappearance of the mutual aid tendency. Mutual aid, though in Prince Kropotkin's opinion somewhat fallen from its high estate by being confused with or contaminated by "charity," is to-day really widespread both in public and private life.

The appearance of this work is most opportune at a time when mutual aid is more needed than ever, and as its price puts it within the reach of even a very modest purse, we hope that it will be widely read and seriously thought over.

LIBRARY TABLE.

A Synopsis of the British Pharmacopœia, 1914, and of the Poison Laws of Great Britain and Ireland. By H. WIPPELL GADD, F.C.S. Eighth edition. London: Baillière, Tindall, and Cox. 1915. Pp. 196. Price 1s. net.—The modesty of the preface of this unpretentious little book almost disarms criticism. After paying compliments to the new Pharmacopœia and conceding that for many purposes the volume itself must be consulted, the author proposes his book as a summary for students and as a pocket reminder for medical men and pharmacists. Within a limited range the book will be helpful to those who wish to read while running, but it will often provoke a desire for more detailed information or for further elucidation of the text. The lack of guidance will be felt most acutely by those who refer to the section on Tests for Chemicals, which gives no information about the composition of the tests employed; we meet with T.S. ferric chloride and with T.S. mercuric chloride, but fail to find any indication of the strengths of these test solutions. On the other hand, the employment of heavy type for the footnotes from the Pharmacopœia which call attention to alterations in strength of official preparations will be a great boon to the young man in a hurry. The synopsis of the laws affecting the sale of poisons is clear and well arranged.

The Mind at Work: A Handbook of Applied Psychology. Edited by GEOFFREY RHODES, with contributions by CHARLES BUTTAR, M.D., E. J. FOLEY, and Professor L. L. BERNARD, Ph.D. London: Thomas Murby and Co. 1914. Pp. 235. Price 3s. 6d. net.—In this little compendium are two chapters by Dr. Buttar on nervous anatomy and physiology, which exigencies of space, no doubt, have rendered almost too concise; nine on elementary psychology, dealt with mainly, or at least to a

considerable extent, from the physiological side, by Mr. Foley; two by the editor (containing much by way of quotation) on the subconscious mind, dreams, suggestion, and hypnotism; and one by Professor Bernard on the applications of psychology to social problems. We feel that the authors would have done themselves and their subject greater justice had the purview of the book been less comprehensive or its individual sections more detailed. It suffers, as a whole, from the brevity with which its subjects are handled. In a short glossary of psychological terms at the end the word psychosis is used in a sense different from that in which it is ordinarily used by the medical profession. Organic sensations are said to be "those that arise from the body itself, as aches and pains," a definition which scarcely defines.

A Manual of Normal Histology and Organography. By CHARLES HILL, Ph.D., M.D., Professor of Histology and Embryology, Chicago Veterinary College, &c. Third edition. London and Philadelphia: W. B. Saunders Company. 1914. Pp. 483. Price 10s. 6d. net.—We have not much to add to our notices of the two previous editions of this book. Doubtless its author intends it primarily for veterinary students, and to this is to be attributed the attention given here and in former editions to the subject of the teeth, as well as the new sections which appear now for the first time on the stomach in ruminants and on the hoof of the horse—this last a very interesting feature, though lying a little outside the needs of the medical student. Other novelties in this edition are said in the preface to lie in the "topics dealing with heredity and sex, glands, blood and lymph." The index gives singularly little help in identifying the sections devoted to these subjects, "heredity" being assigned to p. 26, on which the word does not even occur, while "lymph" is not indexed at all apart from compounds such as "lymph-gland" and so forth. A very simple division of white corpuscles is adopted, without any of the refinements of classification sometimes practised, but we do not mention this as a fault. The best feature of the book is its illustration.

Know Your Own Mind: A Little Book of Practical Psychology. By WILLIAM GLOVER. Cambridge: University Press. 1914. Pp. 204.—Mr. Glover has written a useful little book of everyday psychology, intended to popularise the subject. With this end the matter has been dealt with on elementary lines and in simple phraseology, while numerous practical illustrations and illustrative instances ensure the attractiveness and readableness of the work. It does not pretend to cover the ground completely or equally, but for the immediate purpose it serves very well, presenting that combination of technicality and lucidity which is a sufficient index of the author's own grasp of his subject. The beginnings of mind are discussed, and how ideas get into the mind. Mental machinery is sketched, apperception and what is implied thereby is rather more fully handled, and there are readable chapters on observation, judging, attention, and interest. The author's point of view is frankly Herbartian, but the applications of the teaching are essentially modern and up to date. To the individual of average intelligence and education who wishes to know more of "how it works" this fresh and well-written précis of the mind's activities and diversities may be cordially recommended.

JOURNALS AND MAGAZINES.

Quarterly Journal of Medicine. Edited by WILLIAM OSLER, J. ROSE BRADFORD, A. E. GARROD, R. HUTCHISON, H. D. ROLLESTON, and W. HALE WHITE. Vol. VIII., No. 30. January, 1915. Oxford: At the Clarendon Press; London, Edinburgh, New York, Toronto, and Melbourne: Humphrey Milford. Subscription price 25s. per annum; single numbers 8s. 6d. net each.—The contents of this number comprise: 1. Notes of Further Observations upon Dyspnoea and its Relation to Blood Reaction, by Thomas Lewis and Joseph Barcroft. The influence of reduced alkalinity of the blood or acidosis in the production of dyspnoic states is further examined by means of a study of the percentage saturation of the blood with oxygen when exposed at 37° C. to 17 mm. pressure of that gas. From a study of a series of cases of heart disease the authors conclude that from the point of view of blood reaction and dyspnoea cases of heart disease may be divided into two classes. The first comprises relatively simple and uncomplicated cases in which, though cardiac failure may be present, recovery generally occurs. In this group no acidosis is found. The other group comprises many of the cases of heart failure in middle-aged or elderly subjects, in which reduced alkalinity in the blood is frequently present. It appears, however, that the acidosis is not to be attributed to heart failure only, and that there may be a renal factor in its production. Some observations are recorded upon cases of mechanical dyspnoea, which seem to indicate that acidosis may be a factor even in such cases. 2. Observations on Thomsen's Disease, by W. Johnson and Geoffrey Marshall. In a family of eight children, four were found to be affected with Thomsen's disease, and three of these have been carefully investigated. As a result of their observations, Dr. Johnson and Dr. Marshall suggest that in this disease there is an increased resistance to the passage of nervous impulses, and they believe this resistance to be in the synapses. They found that strychnine has a marked effect in lessening the myotonic character of the contractions. They believe that histological changes in the muscle are secondary effects—namely, a form of compensatory hypertrophy. Their observations lead them to suggest the use of strychnine in the treatment of this disease. 3. The Rationale or Modus Operandi of the Wassermann Reaction and Abderhalden's Test, by J. E. R. McDonagh. From a study of the physico-chemical properties of the individual factors in the Wassermann reaction and in Abderhalden's pregnancy test, Mr. McDonagh offers the suggestion that neither of these reactions is specific, but that they are group reactions which depend on certain physical conditions of the protein molecules. He believes that in the Wassermann reaction we are dealing with a pure precipitation, and in Abderhalden's test with precipitation and hydrolysis. 4. The Metabolism of Nitrogen in Dermatoses: General Review by H. L. Tidy. From a study of the literature the following general conclusions among others are arrived at: changes in the nitrogenous excretion in various dermatoses are the result of the condition of the skin, and are not connected with the cause of the disease. Retention of nitrogen is apparent and not real, and is accounted for by the abnormal excretion of nitrogen by the skin. It is suggested that a low protein diet is worthy of trial in forms of dermatoses where the nitrogenous excretion is disturbed. 5. The Treatment of Congenital Syphilis, by Leonard Findlay and Madge E. Robertson. The results of treatment of congenital syphilis by means of neosalvarsan are analysed, and it is stated that this drug is superior to mercury in alleviating many of the manifestations of the disease. It is advised that the drug should be given intravenously, preferably into the veins of the scalp.

Dental Record.—To the February issue of this journal Mr. C. A. Achner contributes a paper on the light wire splint for fractures of the mandible. The best method of adapting the splint to various types of fracture is shown by a series of stereoscopic photographs. The apparatus was reviewed recently in our columns.—Mr. J. F. Colyer contributes a further instalment of his paper on injuries of the jaws and teeth in animals. Injuries to the tusks of elephants are described, as well as injuries to the teeth of rodents and carnivora.—Mr. Norman G. Bennett has an article on the relationship between the size of the teeth and the size of the jaws. He considers there is reason to uphold the three views that have been put forward to account for the great variation that exists. These views are (1) progressive inherited

changes in the jaws, proceeding more quickly than in the teeth; (2) inheritance of the jaws from one parent and the teeth from the other; and (3) defective growth of the jaw as the result of disuse or environment subsequent to calcification of the teeth germs.

British Dental Journal.—The issue of this journal for February contains a paper by Dr. E. C. Kirk on the Chemistry and Physiology of the Saliva. The author gives a complete résumé of the work on the physiology of saliva which has been carried out in America since 1909. He lays great stress on the composition of the saliva, and considers it a most important index of metabolism. There is a reprint of an article by Dr. C. H. Mayo on Mouth Infection as a Source of Systemic Disease, and a useful paper by Dr. Gilmer and Dr. Moody on the Bacteriology of Alveolar Abscess.

THE ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD FOR 1913-14.¹

I.

THE report of Dr. Newsholme, medical officer of the Local Government Board, recently issued as a supplement to the Board's general report for 1913-14, has already been noticed in THE LANCET in general terms. But many points therein merit special mention. Although the several annual and special reports of the Medical Department are primarily designed for the information and guidance of health officers, they nevertheless abound with records of scientific investigations respecting the nature and prevalence of disease which are of profound interest to every student and practitioner of medicine. The arrangement of matter in the present report corresponds to that in its predecessors—the administrative considerations derived from the experience of the year being set out in relation to the course of events indicated by our national records of sickness and mortality. We propose to comment mainly upon topics which are regarded by Dr. Newsholme as exceptionally important, or which have been only sparingly discussed elsewhere.

Waste of Infant and Child Life.

In the year 1913 English infant mortality was at the rate of 110 per 1000 births, which is somewhat above the rate of 1912, but as compared with previous years the curve is considered satisfactory. Equally satisfactory, likewise, is the aggregate decline of mortality at ages up to five years. From a table based on the experience of 1911 it appears that out of a given total of births the largest number survive to the end of the fifth year in the rural districts, the smallest number in the county boroughs. Fully 88 per cent. survive to that age in the southern division and 83 per cent. in the midland, whilst only 81 per cent. survive in the north of England and in Wales. A statement is added of the relative magnitude of the chief causes of mortality in infancy and early childhood, which throws light on the possibilities of further reducing the waste of child life. From this we gather that over one-fifth of the deaths in infancy, and nearly one-third of the deaths under 5 years, are due to infective diseases, including tuberculosis. Pneumonia and bronchitis, which should also be classed as infective, account for about one-fifth of the deaths under 1 and under 5 years respectively. Solution of the problem of protecting child life and securing correlative improvement in the health of survivors beyond childhood evidently consists largely in the prevention of infections. In these and some other conditions the previous nutrition of the infant is of chief importance, and the factor which determines the result of infection, when acquired, is not infrequently rickets. Study of the now available returns of mortality in early infancy leads to the conclusion that most of the deaths under the age of four weeks are due to causes originating before birth. Comparing the experience of the year 1912 with that of 1905, it appears that in the first month of life the death-rate has fallen by not more than 8 per cent.; in the next two months it has fallen by 29 per cent.; in the second three months by 40 per cent., and in the last half of the period of infancy by 35 per cent. The relatively insignificant decline of mortality

in the first month of life probably indicates that congenital disease and enfeeblement are largely responsible for fatality in this period.

Government Grants in Aid of Preventive Schemes.

At the instigation of their medical staff the Local Government Board have recently devoted serious attention to questions of infant life protection, the well-directed efforts often made by municipal and voluntary agencies for dealing with the matter having been duly appreciated. By the representations of eminent members of the public health service as well as by their own departmental experience, the Board are convinced of the necessity for more extensive and systematic measures than those that have hitherto been practicable. Recognising the inability of many local authorities to bear the entire cost of adequate schemes for the promotion of maternity and child welfare, they are disposed to intervene with direct financial assistance. Accordingly the Board have applied for Treasury sanction for the apportionment of grants in respect of work of this character initiated under official sanction by municipalities or by voluntary associations. They further express their readiness to afford expert advice and assistance to sanitary authorities contemplating the initiation of schemes or the extension of those already in operation. The action of the central authority in thus attempting to provide for one of the most pressing needs of local sanitary reform is a very valuable one.

Infant Welfare Work.

The necessity of safeguarding child life at its origin, upon which depend the health and vigour of survivors at adult ages, appeals with tenfold earnestness in time of war. In view of the remarkable activity recently displayed by local authorities and voluntary agencies for the promotion of maternity and child welfare work, the medical officer devotes considerable space to the consideration of the subject. The development of a comprehensive scheme for this purpose has already been announced in two special reports by Dr. Newsholme² dealing exhaustively with the problem of English mortality in early life. From these documents a close interrelation became apparent at the outset between defective sanitation, poverty, and intemperance on the one hand and excessive infant fatality on the other. Account was also given of efforts already made in this country for reducing the waste of infant life. In his report for 1905-6 Sir William H. Power, at that time medical officer to the Board, distributed to the local medical officers of health improved and considerably extended forms of infant mortality tables for use in their periodical reports, and invited their coöperation in the hope of ensuring success for the new departure. It is gratifying to learn that the response to this appeal has been eminently satisfactory, and has resulted in materially stimulating official study of this previously neglected subject. The statistics compiled since 1905 from the amended tables then issued constitute the basis of comparison in Dr. Newsholme's two recent reports. Appreciative reference is made in the present volume to important early efforts for the preservation of infants in certain towns of the north. As early as 1899 Salford commenced a successful system of voluntary notification of births by midwives. The action of Huddersfield in 1906 in securing the prompt notification of births is another significant indication of the strengthening of public opinion in favour of this measure, and doubtless helped to facilitate the passing of the Notification of Births Act of 1907. By the middle of 1914 this Act had been adopted by most of the principal authorities, and its extension is still rapidly proceeding. Consequent on this extension the number of health visitors has materially increased. In addition to the numerous voluntary workers more than 600 health visitors are already employed by sanitary authorities for the care of infants. This implies that there exists a paid health visitor for every 6000 children under school age in England and Wales. Considerable saving of infant life is known to have resulted from the adoption of this Act, especially in some of the northern industrial centres. The expert advice given by health visitors, whilst primarily beneficial to the infants, is frequently found effectual in securing improved health conditions in the homes visited. In Manchester and Liverpool "infant consultations" are conducted under voluntary arrangement, and in Sheffield periodical consultations are

¹ London: Wyman and Sons. Price 1s. 11d.

² THE LANCET, Jan. 10th, 1914, p. 129.

held, the medical expenses being defrayed by the town council. Under the direction of the Birmingham Health Department infant consultations are held at stated times, and at Bradford there is a municipal infant consultation centre and milk depôt at which three whole-time medical officers and 13 nurses are employed. A new central infant welfare centre is being provided in this town to contain 20 beds for the accommodation of non-infectious patients under school age.

Antenatal Mortality.

Under the Births Notification Act, which provides for the reporting of live births as well as of dead births occurring later than the twenty-eighth week of pregnancy, some estimate is possible of the loss of life preceding birth, in addition to the large aggregate of infant mortality after birth, which is due to conditions arising in the antenatal period. A table in the text indicates the existence of local differences in the ratio of dead births to registered live births, from which it seems that a variable proportion of dead births remain unnotified. Dr. Amand Routh is quoted as estimating that abortions at an early stage of pregnancy are probably four times as numerous as the dead births, which may be taken to average 3 per cent. of the children born alive. This would imply a total antenatal mortality of 150 per 1000 births, which is higher than the average mortality in the first year after birth. The significant recent fall in the English birth-rate has recently been referred to by Dr. T. H. C. Stevenson in his remarks on fertility in relation to social status.³ Evidence was adduced in support of the view that outside the range of extreme poverty the relation frequently observed between high birth-rates and high death-rates is by no means constant or unavoidable. Among agricultural labourers, for example, who constitute nearly 5 per cent. of the entire adult population, the families are of fully average size. Yet their infant mortality is below the general rate by 22 per cent.

Antenatal Preventive Work.

As the result of inquiry the Board are assured that a considerable amount of antenatal health work is locally in progress, especially in connexion with maternity departments and infant consultation centres. In the maternity departments of several metropolitan hospitals provisions exist for the home visitation of expectant mothers, who are attended at intervals both before and after confinement. At St. Thomas's Hospital all women applying for maternity aid are seen by a medical officer, who decides whether a case shall receive hospital or home treatment at her confinement. Home visits are undertaken by voluntary agencies; at these visits, which are highly appreciated, efforts are made to induce the expectant mother to provide suitably for the infant's arrival. The confinements at home are attended from the hospital, the supervision of mother and infant being continued for at least a year. Many of the children are kept under observation up to school age. At Leeds the maternity hospital furnishes a list of women applying for such aid, and these are visited by municipal health visitors at intervals up to their confinement, and in most cases subsequently also. The Leeds Babies Welcome Association have several centres at which expectant mothers are received, and midwives are asked to refer expectant mothers to these centres. Similar arrangements obtain at Newcastle-on-Tyne, Warrington, and St. Helens.

Organisation of Maternity Centres.

Under this heading the medical officer gives helpful suggestions concerning the establishment and management of maternity centres, in respect of which the Board are desirous to afford financial assistance. These institutions are believed to constitute the best practicable means of providing medical care for expectant mothers, as well as for mothers during confinement, and for these and their offspring until the latter arrive at school age. It will be remembered that, in addition to these centres, the salaries of health visitors and officers of infant consultations are among the subjects for Parliamentary grants. In order that the necessary information may be obtained regarding expectant mothers for whom medical assistance is required, the close

coöperation of the local midwives is indispensable. In all cases it is essential to aim at securing adequate medical aid and guidance for both mother and child, from the birth of the latter onwards, both by means of home visitation and by attendance at a maternity centre for medical advice and treatment if necessary. The overlapping of duties with those of other voluntary agencies must of course be avoided.

Mortality in Connexion with Maternity.

The national death returns furnish conclusive evidence of the need of additional maternity work, whether the figures for infantile or for maternal mortality are compared: Nearly all the deaths in the first week, and most of those in the first month of life, are due to natal or antenatal causes. Of the total deaths in the first year about one-fifth occur in the first week, and one-third in the first month after birth. That this sacrifice of life is largely avoidable is proved by the great variations in incidence shown by the tables in various parts of the country. With respect to adult loss of life in connexion with maternity we learn that the deaths assigned to pregnancy and childbirth in 1912 amounted to 3473, or 3.98 per 1000 births, of which number 1216 were caused by puerperal septicæmia. Of late years there has been a reduction in the death-toll from these diseases, but it remains an unsatisfactory fact that even so recently as 1912 septic conditions in childbirth accounted for the loss of 1216 English mothers. Moreover, it is common knowledge that a vast amount of suffering of indefinite yet disabling character is caused by unskilled attendance in labour, and by failure to recognise septic and other conditions complicating pregnancy and childbirth.

(To be concluded.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

AN ordinary meeting of the Council was held on Feb. 11th, Sir W. WATSON CHEYNE, the President, being in the chair.

It was resolved to issue Diplomas of Membership to 112 successful candidates.

It was also resolved to issue jointly with the Royal College of Physicians Diplomas in Public Health to six successful candidates.

In accordance with the recommendations of the Anatomical Committee, which was appointed last December to consider what steps should be taken to increase the present inadequate supply of subjects for dissection, it was resolved to write to the Secretary of State for the Home Department pointing out the importance of the matter and expressing the hope that steps might be taken to remedy the deficiency.

Mr. John Murray, surgeon to and lecturer on surgery at Middlesex Hospital, was elected a member of the Court of Examiners.

Mr. Charles Alfred Ballance was elected from the members of the Court of Examiners a member of the Board of Examiners in Dental Surgery.

A letter was read from Mr. T. Egerton Bryant thanking the Council for their resolution of sympathy on the death of his father, Mr. Thomas Bryant.

The PRESIDENT reported that in pursuance of the provisions of the Bradshaw Bequest he had chosen Sir Anthony A. Bowlby as Bradshaw Lecturer for the ensuing year.

DUBLIN LECTURESHIP IN OPHTHALMOLOGY.—

The late Robert John Montgomery, M.A., M.B. Dub., F.R.C.S. Irel., bequeathed to the Board of Trinity College and to the President, Vice-president, and Council of the Royal College of Surgeons in Ireland a sum of money for the establishment of a lectureship in ophthalmology in Dublin. He desired that the lectureship should be known as the Mary Louisa Prentice Montgomery Lectureship in Ophthalmology, and that the appointment to it should rest each alternate five years with the Board of Trinity College and with the president, vice-president, and Council of the Royal College of Surgeons in Ireland. Joint regulations have been drawn up by these two bodies and the first election to the position will take place at the beginning of next summer session. The salary amounts to about £160 per annum.

³ Registrar-General's Annual Report for 1912, p. 22. THE LANCET, Sept. 12th, 1914, p. 707

THE LANCET.

LONDON: SATURDAY, FEBRUARY 20, 1915.

Antityphoid Inoculation in the Army.

THE reopening of Parliament has enabled responsible Ministers to indicate the general attitude at present adopted with regard to antityphoid inoculation in the army, and from their answers to questions asked in the House it is easy to realise the trend of thought for the future. For the present Lord KITCHENER commends to the careful attention of every soldier a statement to which he attaches great importance in the interests of the health of the army. The probable development in the future may be gathered from the remark of Mr. TENNANT, Under Secretary of State for War, that evidence is accumulating in favour of making inoculation compulsory, and it is clearly indicated that the House of Commons will be afforded an opportunity of expressing an opinion on this matter. It is perhaps unfortunate that discussion should be deemed necessary, and still more unfortunate that the term "compulsory" must be employed. Discussion is not likely to convince those who approach the debate with a mental kink against what has been termed the arrogance of science; still the outcome of debate must be a foregone conclusion since the evidence in favour of inoculation is overwhelming. Public discussion is not likely to serve any useful purpose, for remarks made in the course of criticism, will assuredly be seized upon, separated from their context, and reproduced in distorted form by those who are actuated by objects far removed from the immediate subject—namely, the advisability of compulsory antityphoid inoculation in the army as a prophylactic measure. It is often assumed by honest critics that some occurrence of typhoid amongst those protected by inoculation is sufficient to discredit this form of treatment. Further study of the great diminution in frequency, severity, and mortality should convince those who are open to conviction. Omnipotence has never been claimed by any scientific man for any form of treatment. It would be equally unsound to question the general advisability of operations for appendicitis or of the adoption of Listerian methods because certain fatalities have occurred when treatment has been unduly delayed or when there has been some lack of technical precautions.

Under ordinary circumstances the mere suggestion of "compulsion" is sufficient to rouse a storm of invective and antagonism. The average man, accustomed to believe that he is a free agent, living

in a free country, resents any interference with this belief, and yet, on consideration, he has to admit that the conditions of civilised life leave very little room for the exercise of irresponsible freedom. In times of peace any threatened interference with liberty of action affords a healthy stimulus for discussion and fosters party feeling. The language of the battlefield is used with complacency, the nation is said to be divided into hostile camps, and the gains and losses of the parties are recorded daily. With the declaration of war the national spirit asserted itself, and opponents stood shoulder to shoulder to meet the common foe, and all the minor interests of the past were overshadowed by the urgent needs of the present. Criticism was respectfully hushed and all combined to support the authority of the executive officers of the Crown. Circumstances now are affording an opportunity for the troublesome activities of a minority opposed to scientific progress. The comparative pause which has accompanied the deadlock in the trenches has naturally been utilised by the authorities in fitting the new army for active service and in endeavouring to strengthen the powers of resistance of those already engaged. Those who were silent in the early realisation of a common danger have recovered the desire to attack measures advocated by those in authority. With vague ideas that in some way antityphoid inoculation is connected with vivisection a veritable crusade of an unworthy character has been started, and it is urged that inoculation and vaccination have impeded the course of recruiting. Last week we published a leaflet to the troops, which Lord KITCHENER had commended to the careful attention of every soldier, and consideration of the eminence of those who signed the statement should be sufficient evidence of its value. Each individual soldier is told that, "For your own sake, for your country's sake, and for the sake of the Army you should not fail to avail yourself of the protection secured by this simple, safe, and well-tested measure." This is the language of persuasion and of reason, expressed in very temperate terms, and it assumes that good sense will prevail over prejudice, and that it may not be necessary to resort to compulsion. Had an additional argument been required, it might have been pointed out that the force of example was not wanting; that while men of all classes and ages have been enlisting, or undertaking some form of personal sacrifice by which they hope to be able to feel that they have contributed their share in safeguarding the nation, officers and medical men have, in addition, been inoculated to minimise the risks of exposure to infection.

The leaflet makes the personal appeal to the individual for his "own sake," but it would be well for him to realise that the reference to the country and the army is no mere rhetorical flourish. The care of each individual in the field is of immense importance, since sickness removes not

only one and the many who have to care for him, but it also serves to demoralise others, who may doubt the efficacy of the sanitary measures adopted to check the spread of an epidemic. Doubtless it is hoped that the leaflet will facilitate future measures by preparing the mind of the individual soldier for a general order. It will serve a good purpose if it shakes the belief in the truth of the "literature" circulated by opponents of vivisection, against whom, as indicated in the House of Commons, action conceivably might be taken for an attempt to impede recruiting and to stir up discontent amongst those actually on service in the field. So far as recruits are concerned, the term "compulsory" is not strictly applicable. Inoculation might be made one of the conditions of service, and these conditions, like those of height, weight, or chest measurement, can be altered at will. It might be inserted among the requirements for all likely to go on foreign service, since it is amongst those who serve at the front the risk of an epidemic is greatest, and that its occurrence tends to dislocate the most carefully prepared organisations. The difficulty that has to be faced is the enforcement of a new regulation which would affect those already in the field. So long as there is any room for the exercise of individual option, so that a single "conscientious objector" may by himself serve as a source of danger to the whole expedition, all efforts to influence by the force of reason are likely to be nugatory. In the light of our experience in South Africa, and in view of the evidence collected in America, it is sincerely to be hoped that, if Lord KITCHENER desires, Parliament will strengthen his hands in sanctioning any new regulation which will give effect to the representations he has received from his scientific advisers.

Gunshot Wounds of the Head.

MODERN small-arm projectiles are in some respects less injurious than those which were used 50 years ago, for if a modern bullet passes through a limb without encountering a bone, or a large vessel, or an important nerve, little harm may result, and recovery may be complete in a short space of time. With wounds of the skull, however, it is far otherwise. The modern bullet, though much smaller than its predecessors, travels with a velocity far beyond anything known until recent years, and when it reaches the skull it produces results which surprise us by their severity. Even now, though several wars have been fought with these modern weapons—and in the present war we have had some six months' experience of the effects of rifle bullets—yet it cannot be said with certainty that we are fully acquainted either with the mechanism of the bullets' action or with the most suitable method of treatment.

It was practically useful and scientifically interesting that the Medical Society of London held last week a debate on the subject of gunshot

wounds of the head. As to the mechanism of the action of the bullet we had the results given us of some interesting experiments which Sir VICTOR HORSLEY had performed, a full description of which will be found in our issue this week. He chose a modelling clay as not very dissimilar in consistence from the tissues under consideration, and into a mass of this he fired bullets resembling those used in modern war, and he obtained some surprising results. The most striking point brought out by his researches was the fact that much of the harm done to the tissues by the bullet is due to its rotation rather than to its onward movement. Further, he attributes the varying effects of different bullets solely to the difference in sectional area, and not at all to the shape. The so-called explosive effect which is so striking a result of the modern bullet has been shown to be due to the fact that the brain has somewhat of a fluid nature, containing indeed a large proportion of liquid in its composition. Therefore, when the entrance of a bullet into the skull suddenly increases the intracranial pressure, this increase of pressure is transmitted with hardly any diminution in all directions, and the explosive action is brought about. Though much of all this is theoretical, the practical point as to what is the best treatment of a gunshot wound of the brain ought to be decided upon an understanding of the mechanical factors.

Treatment of bullet wounds of the head is at present regulated upon general lines, with due regard especially in the matter of prognosis to the special conditions. Sepsis in any part of the body is serious, but nowhere is it more serious than in the cavity of the skull, and it was generally agreed by speakers at the discussion at the Medical Society that a thorough attempt should be made at the earliest possible moment to cleanse the track of the bullet and to remove fragments of bone. What antiseptics are to be used must depend on the surgeon, but the cleansing must be thorough, and if this be done the chance of recovery is greatly increased. The other main harmful factor in the production of symptoms from cranial injury is the rise of intracranial pressure; this comes partly from the effusion of blood and partly from exudation, and when this rise of pressure is excessive it is essential that decompression should be practised at the earliest possible moment. Sometimes it is sufficient to clear the openings in the skull caused by the bullet; sometimes trephining must be done. An important suggestion in the treatment was brought forward by Mr. W. H. H. JESSOP at the debate at the Medical Society, when he pointed out that in cases of fracture of the vault by bullet or shrapnel there was an early papilloedema, pointing to increased pressure, but that this papilloedema rapidly disappeared when decompression had been practised. In such cases, even when the cedema is well marked, no symptoms may be present, a point of the first

practical importance. We trust that the whole subject will, at some short interval, be again discussed by representative surgeons in order that this kind of practical suggestion may be widely forthcoming from different experts, while the sad circumstances in which we live render material for debate available.

Annotations.

"Ne quid nimis."

THE FOOD-SUPPLY OF THE GERMAN PEOPLE.

WE publish this week a detailed review of Dr. Paul Eltzbacher's remarkable pamphlet on the food-supply of the German people. This work is a complete and authoritative exposition of the situation which he and his collaborators foresaw might arise when the British Fleet began to exercise serious pressure upon the German resources. The figures are as striking as the arguments, and sufficiently show how enormous the task of the Allies has been.

THE BACTERIOLOGY OF CONDENSED MILK AND MILK POWDERS.

A REPORT concerning the effects of certain condensing and drying processes used in the preservation of milk upon its bacterial contents was issued last week by the Local Government Board. The investigation was undertaken by Dr. Sheridan Delépine. The three methods of preservation examined were: (1) the manufacture of sweetened condensed milk; (2) the drying of milk over heated revolving cylinders; and (3) the drying of milk by spraying it into a current of hot air. The experiments now reported were made with the view of ascertaining whether tuberculous cows' milk was still capable of conveying tuberculosis after being treated according to methods 1 and 2. Further experiments have been made on the general effects upon the bacterial contents of milk following the use of methods 2 and 3, but the results await further inquiries. In feeding experiments Dr. Delépine reports the superiority of dry milk over fresh milk, and points out the advantages of dry milk from the hygienic as well as from the commercial point of view. It is therefore regrettable, he adds, that the process of drying should not always yield an article entirely free from pathogenic bacteria. He concludes that if clean milk obtained from healthy cows were dried in a factory where suitable precautions were taken to prevent recontamination, dry milk almost free from bacteria could be produced. No experiments appear to have been made on the question of how long in a practically dry powder the organisms remain virile. The activity of bacteria is necessarily diminished in the absence of moisture, and milk powders do not, as a rule, contain more than 3 or at the most 5 per cent. of moisture which can be expelled by heat. In summarising his work Dr. Delépine states that the total number of bacteria present in mixed cows' milk has been found to be considerably reduced by treatment according to each of the three methods investigated. The reduction was greatest in the case of sweetened condensed milk, least in the powder obtained by spraying milk into hot air,

while milk dried over hot cylinders occupied an intermediate position. In each of the three methods of treatment there was a stage at which the reduction in the total number of bacteria was much greater than that observed in the finished article ready for sale. This increase is attributed to recontamination. The interesting observation is made that the tubercle bacilli which had survived pasteurisation in method 1 and drying by heat in method 2 were still capable of producing progressive tuberculosis in guinea-pigs inoculated subcutaneously with milk containing these bacilli, but the course of the disease produced by these organisms was very much slower than that of the disease produced in guinea-pigs inoculated with the same amount of untreated tuberculous milk. The tuberculosis produced by the heated bacilli was "latent" or "occult" for some four weeks, while young rabbits fed with milk containing these modified bacilli did not contract tuberculosis. The report forms a valuable addition to the series of food reports issued from time to time by the Local Government Board, and it appears clear that if precautions were taken to guard the condensed or dried milk products from recontamination they would, generally speaking, be safer to use than raw milk.

EPILEPSY AND OPERATION UPON THE FEMALE PELVIC ORGANS.

IT is stated by some writers that the development and commencing activity of the female sexual organs are in some way concerned with the onset of epileptic convulsions. It has also been said that the time at which the menses cease to appear is again apt to be attended with the occurrence of epilepsy, but Nothnagel denies that this is the case. It would not be difficult to find a number of cases recorded in medical literature in which the onset of epileptic fits coincided with great accuracy with the occurrence of the menstrual period. Cases, too, are to be found in which the fits have ceased during a pregnancy, only to recommence with the return of the monthly periods. When we bear in mind the increased nervous excitability of the woman at the menstrual period, and further, when we remember the tendency to periodic recurrence of epileptic attacks and the periodicity of the monthly periods, it is not surprising to find that in a certain number of women the two conditions coincide so frequently as almost to lead to the conclusion that there is some definite relationship between them. There is, however, no certain proof of any etiological relationship between uterine and ovarian disease and epilepsy. Sir William Gowers said, "Of epilepsy due to disease of the uterus or ovaries nothing is seen except by gynaecologists," and from the point of view of a judge demanding evidence the statement stands. In spite of this opinion from so high an authority a number of cases have been recorded in which various operations have been carried out upon the pelvic organs of the woman for the purpose of curing epileptic fits. Dilatation of the cervix, the treatment of erosions, the amputation of the cervix, and even the removal of the healthy ovaries have been advocated, and indeed practised, from time to time with reputed benefit to the patients. That the fits have ceased and in some cases have never returned has been adduced as proof of the value of the particular procedure

adopted. It is, however, important to remember that the same may be said for many different operations, and it has been shown that any surgical procedure on any part of the body may influence favourably, for a time at any rate, the course of epilepsy. Osler quotes White as having collected a series of cases in which such diverse operations as ligation of the internal carotid, circumcision, castration, tracheotomy, excision of the superior cervical ganglion, and incision of the scalp have all been practised, often with good results. The extraction of a carious tooth has not infrequently had an equally good effect, or a treatment for worms. Fagge mentions the case of an American who had been castrated and treated with nitrate of silver in the hope of curing his epilepsy. His skin looked as if it had been polished with blacklead, but the result of the combined treatment was negative so far as the disease was concerned. A recollection of these and many similar facts concerning the operative treatment of epilepsy should prevent any gynaecologist who is careful to take a broad-minded view of his patients, and who has freed himself from the old and utterly erroneous belief, "*mulier tota in utero*," from practising the operation of removal of the healthy ovaries for the cure of epilepsy. The old-fashioned term "spaying" has rather dropped out of use at the present day, but if the enterprising surgeon who contemplates this operation will recollect that he is in reality spaying his patients he may think twice before carrying out such treatment. Naturally, if the pelvic organs are diseased and require removal this should be done, and if the patient also suffers from epilepsy she will no doubt derive benefit from the operation, and may even be cured for a time or completely of her convulsions. This is, however, no argument for the removal of healthy ovaries, and we should not have believed that such an operation was practised at the present day had not a correspondent written to ask our opinion of this procedure. If the pelvic organs are diseased in a case of epilepsy any necessary medical or surgical treatment should be carried out coincidently with the appropriate medical treatment for the disease. In a very few rare cases in which the genital tract is so malformed that the patient can never marry, as, for example, with absence of the vagina, and where at the same time she suffers from epileptic attacks recurring at monthly intervals, oöphorectomy might be justifiable. The removal, however, of the healthy ovaries, when a normal genital tract is present in an otherwise healthy woman, in the hope of curing epilepsy, is not likely to be successful and is never, in our opinion, necessary or justifiable.

GRADUATED EXERCISES AT OUR HOME HEALTH RESORTS.

THE observation that so many of our home health resorts present ample facilities for a course of graduated exercises in functional disorders of the heart is opportune and should receive careful consideration. In an interesting paper which Mr. J. S. Kellett Smith has sent us he refers, for example, to the extreme suitability of Eastbourne for the treatment of favourable cases, and there can be little doubt that other seaside health resorts present similar opportunities when their environment comes to be carefully studied. As Mr. Kellett Smith points out, even under normal circumstances it is not every patient who can visit a continental health resort,

and it is not every case that can stand the journey. But a preparatory course—resisted exercises, massage, carbonated baths, or Bergonié treatment—can be given locally if necessary, and in addition to a favourable situation—near the sea-level and sheltered from the prevailing winds—and a mild winter climate, the disposition of the ground in many of our seaside places probably offers an excellent arena for carrying out the exercises for the terrain cure. With this object in view he has mapped out a course at Eastbourne, giving the various gradients on the parades and sea front, beginning with gentle exercises and ending with a more rigorous treatment by gradually bringing the patient to accomplish a stiff climb on the Downs and to Beachy Head. The principle throughout is to strengthen the heart by making it work with a lightened load, this being obtained by restriction of fluids when necessary and by the dilatation of the peripheral vessels in the big muscle groups and skin produced by exercise. Exercise is given by walking along roads of graduated steepness, commencing at level and progressing to hill-climbing, the activity and distance being increased as the case improves. The suggestion seems to us to be an admirable one, and should set other seaside authorities thinking.

THE FUNCTIONAL CAPACITY OF THE KIDNEY.

THE problem of investigating the functional activity of the kidney is admittedly a difficult one in view of the uncertainty which still dominates the definition of the renal function, which some consider to be under the influence of simple physical or physico-chemical laws, while others contend that it is controlled by laws, mysterious and unknown in their essence, like those which are attributed to the so-called vital energy. Dr. L. Pezzana¹ has studied the application of the phenolsulphonphthalein test to this question, and considers it markedly superior to all others for estimating the functional capacity of the kidney from the point of view of its facility and of rapidity of elimination. Phenolsulphonphthalein, discovered by the American Ira Ramsen, was first proposed for the study of the renal function by Rowntree and Geraghty, who proved its harmlessness and exclusive elimination by the kidney. It is administered by subcutaneous, intramuscular, or intravenous injection in doses of 6 mg., and in normal conditions is completely eliminated in from two to four hours. In the urine phenolsulphonphthalein is discoverable by simple alkalisation, and the quantity also may be easily estimated by means of a suitable colorimeter. The patient is made to drink 200 to 300 c.c. of water and then to micturate so as completely to empty the bladder, prior to the injection being made, preferably into the gluteal muscles. The urine passed after 6–10–15 minutes is received into vessels containing a few drops of solution of caustic soda, and the moment when elimination begins is shown by the red colour imparted to the urine as soon as it comes into contact with the alkali. For the estimation, the urine passed in the first hour is collected, 10–15 c.c. of a 15 per cent. solution of sodic hydrate added, and diluted with water to a litre; a portion of this is then placed in the colorimeter, which gives the actual percentage eliminated. The same is done with

¹ Il Policlinico, vol. xxi., 1914, Medical Section, Fasc. 12, December, 1914.

the urine passed during the second, third, and fourth hours. The normal colour of the urine does not usually affect the colorimetric estimation even in cases when the samples only contain 10-20 per cent. of the substance and satisfactory practical results can be obtained. In cases of abnormal colouration, however, from jaundice or blood, it is better to decolourise the urine with animal charcoal or precipitate the pigments by acetate of lead. The results of the author's researches in cases of nephritis show that neither in the acute nor chronic forms does the kidney ever become impermeable to phenolsulphonphthalein, but there is a marked delay in its elimination, and a still more marked diminution in the total amount eliminated. By applying the test in cardiac affections, with and without perfect compensation, an important fact was elicited. In both these classes of case the elimination was good, although the total quantity was slightly below normal, and whereas in the latter class clinical methods showed renal stasis in a marked degree the test proved that the functional capacity of the kidney was very much greater than in cases of nephritis, even where examination of the urine did not disclose any serious changes. This fact shows the value of the test in those cases where great diagnostic difficulty occurs as to whether renal changes are secondary to stasis, and therefore to the cardiac condition, or whether the latter condition is not on the contrary secondary to the nephritis.

THE MEDICAL SCHOOL OF MELBOURNE UNIVERSITY.

IN 1852 Dr. Anthony Colling Brownless, a distinguished student of St. Bartholomew's Hospital, settled in Melbourne, and in 1855 he became a member of the council of the recently founded University of Melbourne which had been established two years previously, and at once devoted his energies to bring about the establishment of a medical school. On his motion it was ordered in 1856 that lectures in medicine should be delivered in the ensuing year. Dr. Brownless in 1857 submitted a scheme providing for professors of anatomy, physiology and pathology, materia medica, therapeutics and dietetics, and a staff of lecturers; but when an application was made to the Government for a grant of £21,000 for the erection and equipment of the necessary buildings, it was objected that the time was not yet ripe, so the grant was not forthcoming. In 1858 Dr. Brownless became Vice-Chancellor of the University and efforts to obtain Government assistance were repeated but without success. In 1861 the Medical Society of Victoria took the matter up, and after discussion with the medical school committee, now organised as a definite body, it was determined to start the school at once though on a modest scale, the cost of the buildings not to exceed £4000, and the scheme submitted by Dr. Brownless in 1857 was accepted on this basis. On account of a falling off in the revenue it was stated again that funds for the buildings could not be provided. The Vice-Chancellor suggested a general retrenchment of expenditure, and the university lecturers on law and civil engineering generously gave up a portion of their salaries to assist in the formation of the medical school. In 1862 a five years curriculum was laid down, with five examinations for the degree in medicine. Dr. John Macadam was appointed lecturer on chemistry, and on the

nomination of Sir James Paget and Sir Richard Owen Dr. George Britton Halford was appointed professor of physiology. From this time onward progress was rapid. In 1863 the medical school buildings were begun, and in 1864 the Melbourne Hospital opened its arms, though without any excess of enthusiasm, to the first batch of third year students. In that year the medical school buildings were completed, and this was the date chosen by the Medical Faculty of the University as the point from which its jubilee, celebrated last year, should be computed. An interesting account of the jubilee has been published in book form.¹ Sir Harry Brookes Allen, M.D., Dean of the Faculty of Medicine, traces the history of the school in detail, with many interesting pictures of the buildings in earlier and more recent times and many portraits of those to whose devoted services the progressive building-up of this school to its present high standard is due. An amusing echo of the mid-Victorian conflict between religion and science" is related by Professor Allen. When Professor Halford in 1869 applied to the council for permission to give a public lecture on "Protoplasm" it was refused on the ground that "matters of politics or religion should be avoided." Melbourne University was early in the field in the encouragement of women medical students, and Mr. Grice, the president of the Melbourne Hospital, pays a high tribute to the great credit its women graduates had brought to the school and to the high average place they had attained in the class lists.

MASTITIS DURING PREGNANCY.

FEW cases have been recorded of mastitis during pregnancy. In the *Boston Medical and Surgical Journal* of Dec. 24th Dr. B. R. Whitcher has reported the following case. A rather poorly nourished woman was seen on Feb. 2nd, 1913. She was of nervous temperament and subject to dyspepsia and constipation. She had been married in the previous November, and had a fall in which she struck her right arm against her breast. Ever since a spot, which was sore and tender, especially at the time of menstruation, remained. On examination a hard nodular lump was felt to the inner side of the nipple. Under ichthyol and belladonna ointment the symptoms were greatly relieved. In October, 1913, she became pregnant. In April, 1914, she was again seen for a tense, brawny, and very tender lump on the inner side of the right breast. Ichthyol and belladonna ointment were again used, but the lump became more painful. As it was thought that the pain might be due to early lactation aggravating the old injury, the breast pump was applied and half an ounce of milky fluid was drawn off with considerable relief. After a few days the lump began to enlarge and became redder and more brawny. On May 10th an incision was made under ether and nearly 3 oz. of pus escaped. A counter-opening was made for free drainage and gauze wicks were introduced. Healing was complete by June 5th. Two other abscesses formed—one outside the nipple, the other in the upper and outer quadrant. It was arranged to operate on them on June 14th, but labour came on and was perfectly normal. On the following day there was so much pain that the abscesses were opened and drained. The infection was of the

¹ University of Melbourne Medical School Jubilee, 1914. Melbourne: Ford and Son. Pp. 108.

diffuse interstitial type. Dr. Witcher refers to the few recorded cases of abscess of the breast during pregnancy—all in American or German literature. In one case an abscess developed in the ninth month after an attack of facial erysipelas. In another double mastitis followed eczema of the nipples in the sixth month. Incision of the right breast yielded pus, of the left turbid fluid. A primipara developed an abscess after being scalded with hot coffee. In all the cases hand-feeding of the child had to be adopted. The etiology of abscess of the breast during pregnancy appears to be as follows. In the majority of women pyogenic organisms are present on the nipples and in the milk ducts in greater or less number, according to the habits of cleanliness. In some cases organisms may be present in the blood stream. As a rule, these organisms are innocuous, especially when there is a general condition of good bodily resistance. But when engorgement of the breast occurs conditions favourable to their growth are developed, and when the breast is injured before or during pregnancy the resistance is still further lowered. In the case reported by Dr. Witcher the underlying cause was the injury to the tissues of the breast, which never regained their normal condition. Possibly the ill-nourished patient had pyogenic organisms in her blood, for she had also an abscess of the finger. In the first case quoted, with such an infection as erysipelas the blood may have contained organisms. In the second case infection probably took place through the eczematous nipples. In the third case there was no visible solution of continuity at the site of the burn. Probably the organisms were already present in the milk ducts and attacked tissues the resistance of which was lowered by the burn.

CONGENITAL HEART-BLOCK.

MORE than ordinary interest attaches to the report by Dr. T. R. Whipham¹ of two cases of congenital heart-block. We believe that the first case, aged 2 years 2 months, is the youngest on record in which the definite proof of heart-block has been established. In this case, a well-nourished and full-time female, the pulse was slow, full, and regular. The heart-rate varied between 48 and 80 at different times. Over the præcordium a loud systolic murmur was audible with maximum intensity near the left sternal border, between the apex and the pulmonary area. Admitted into hospital with whooping-cough and some bronchitis, the pulse still remained at only 64 per minute. Fits of coughing did not quicken the rate; no cardiac symptoms were ever noted. There was a polycythæmia of 8,400,000 red corpuscles, and hæmoglobin was 110 per cent. The electrocardiogram showed definite 2:1 heart-block; that is to say, the auricular rate was twice that of the ventricular. The cause of the block was attributed to a congenital defect, possibly a patent inter-ventricular septum, involving the auriculo-ventricular bundle in that vicinity. The murmurs would depend on this and not, of course, upon the incidental heart-block. The interest of the second case, of a girl aged 12 years, in whom a complete heart-block was proven by galvanometric methods, was that there was reason to believe that such a block had existed for six years, yet it was only at the

age of 11½ that any cardiac symptoms occurred. These showed themselves as pain around the heart on exertion. The pulse-rate lay between 50 and 60 per minute and was slightly irregular, whilst in this case, as in the other, there was a loud systolic murmur of maximum intensity in the fourth interspace near the sternum. The same pathological cause is suggested for this case—namely, a congenital defect.

THE Council of the Royal College of Surgeons of England has granted permission to the Fellows of the Royal Anthropological Institute and to the Members of the Prehistoric Society of East Anglia to hold a combined meeting in the museum and theatre of the College on Feb. 23rd. Many recently discovered specimens will be shown and discussed. The meeting commences at 2.30 P.M. On the evening of the same day the combined societies will meet at 8.15 in the rooms of the Royal Anthropological Institute, 50, Great Russell-street, W.C., when Mr. Charles Dawson will give an account of the various types of implements and cultures met with in the deposits along the valley of the Sussex Ouse—including what may be described as the "Piltown" culture.

Lord Lamington has been elected a trustee of the Museum of the Royal College of Surgeons of England in the place of Sir Edward Fry, resigned.

HISTORY OF PUBLIC HEALTH IN DUBLIN.

IN an appendix to the annual report on the health of Dublin, noticed in THE LANCET of Jan. 9th, Sir Charles Cameron gives some interesting information on the history of public health administration in Dublin. The first trustworthy information on the state of health of Dublin dates from 1798, when the Rev. James Whitelaw made a careful survey of the city, and in his report drew attention to the shockingly insanitary condition of the tenements occupied by the working classes. Matters appear to have changed little in the next half century, for in 1845 Dr. Thomas Willis, in a book on the "Social and Sanitary Condition of the Working Classes in the City of Dublin," spoke of the working classes as "sunk into that state of abject misery for which there is no parallel in any country in Europe." Within the next 20 years the municipal authorities began to show some sporadic interest in the health of the city, and in 1864 Edward Dillon Mapother was elected the first medical officer of health, and ten years later Sir Charles Cameron succeeded him. It was not, however, until 1879 that the statistics of mortality could be regarded as accurate. In that year the death-rate from all causes was 37.5 per 1000, and from nine specified infective diseases 6.2 per 1000. In the following year both rates reached their maximum—37.7 and 7.9. Thereafter they gradually sank, and in 1913 the general death-rate reached its lowest point—20.3 per 1000, and the zymotic death-rate was 2.4. The lowest zymotic rate was in 1905—viz., 1.5. It is noteworthy that within the past few weeks the general death-rate has approached 40 per 1000. Sir Charles Cameron furnishes an account of various activities of the Dublin corporation, which have had an important effect on the sanitary condition of the city. Of these the chief are the supply of the excellent Vartry water brought to Dublin in the late sixties; the substitution of a water-carried sewage system for the old system of privies and ash-pits; and the recent introduction of a system of main drainage by which the sewage is discharged after precipitation into the bay instead of directly and untreated into the Liffey in its course through the city. Sir Charles Cameron also details the various steps taken by the corporation since 1881 to improve housing conditions in Dublin.

¹ Proceedings of the Royal Society of Medicine, Section for the Study of Disease in Children, December, 1914.

THE FOOD-SUPPLY OF THE GERMAN PEOPLE.

(FROM A SPECIAL CORRESPONDENT IN A NEUTRAL COUNTRY.)

In a pamphlet¹ of nearly 200 pages published at the end of the year 1914 Dr. Paul Eltzbacher, acting Rector of the Berlin High School, has edited an authoritative statement on the food-supply of the German people and England's plan to starve them out. In the preface he states that the problem is only to be solved by "combination of the politician, national economist, statistician, physiologist, farmer, geologist—yes, even the experienced housewife," and to this end he has put under contribution members of various faculties, amongst whom the name of Rubner and Zuntz will stand out as well known in the domain of hygiene and physiology. A paper band round the volume states that the book is intended to "show the seriousness of the situation and the means to assure our food-supply," and the whole is the result of four months' work in which, "after initial differences" of opinion, all the writers were finally "united on all essential points" and in the common aim that the "success of our weapons should not be spoiled by economic mistakes." The whole forms an exposition of the problems of a nation's food-supply with such wealth of information and authority as can hardly ever have been brought to bear before on the topic.

Chapter I. states under three headings

The Problem of an Isolated Political Economy.

1. The first deals with the *starvation plan*. Germany and Austria are completely surrounded by hostile lands except for five small neutral countries on whom no reliance can be placed. Germany in normal times has 21 milliard (£1,050,000,000) and Austria 5 milliard (£250,000,000) marks of external trade, and difficult as it might be to do without exports it might be impossible to exist without imports. The plan originating in England was stated more frankly in France, where the physiologist Charles Richet wrote in the *F. garo*: "Before nine months are out Germany will be on her knees suing for peace, unless indeed already speechless with hunger."

2. The second section deals with the conception of *Germany as a closed economic area* which must arrange to do the best it can for itself and by itself. Austria is in relatively less danger with its thinner population and larger agriculture. Germany's relation of external trade to population being three times greater. The "conquered lands" cannot be relied on for food with starvation already setting in. Denmark has already forbidden the export of barley. England states that she can last out indefinitely, and even though she may have made a miscalculation as regards the loss of German dyestuffs and her business as middleman, yet it would be unsafe to reckon on a short war, and Asquith may have weighed his words before he spoke of a possible 20 years. "The best means to shorten the war is to prepare for a long one."

3. The *problem of an isolated political economy* is a new one for economists and statesmen. The modern fashion has been to think of the "world-wide" and the "personal," and internationalism and individualism have filled the field to the exclusion of nationalism. Now all this is changed; production must give place to consumption as the leading idea, and the supply of labour where needed becomes more imperative than the problem of unemployment. The foundation of non-profitable businesses may become a necessity, e.g., the drying of potatoes or the manufacture of nitrogenous manures. The freedom of the individual must be limited for the benefit of the State. "At this time everyone is, so to speak, a

socialist." Export must be prohibited and maximum prices fixed, as well as even more drastic measures. In considering how all this may be done no optimism is permissible. "We must reckon not only with bad weather for the harvest, but also with a lack of skilled labour in the fields, of horses, and of manure, affecting the yield." The organisation of the people's food must not fail.

Chapter II. deals in greater detail with

The Reduction of the Food-supply.

1. *Reduced import.*—The import of fodder, amounting yearly to 10,000,000 tons, must largely cease, although the Baltic is still available, and at present increasingly so. The conception of conditional contraband keeps back most foodstuffs from direct import, nor can the small neighbouring neutral countries be expected to do much more than cover their own needs during the war. Belgium is the most thickly populated country in the world, and Russian Poland does not stand far behind. Roumania's supply of provisions will be entirely swallowed up by Austria.

2. *The home production of foodstuffs.*—The North Sea fisheries have been reduced to a minimum. Agriculture must also suffer from the lack of skilled labourers, horses, and manure. The farm labourer cannot at first be replaced by other workers, although his place may possibly be taken by prisoners of war from agricultural districts. Half a million horses have been taken by the army, and the usual annual import of 140,000 from Russia cannot be counted on. For manure four products are necessary. Potash and lime we possess in abundance, being, indeed, the chief exporting land of potash salts. On the other hand, there is a lack of phosphoric acid and of nitrogen. Phosphoric acid is normally covered by the supply of Thomas-slag, a by-product of the iron industry, and to the extent of one-third by the import of foreign phosphate. Some compensation may come from the Belgian iron fields and crude phosphates, but a deficit will probably remain. Nitrogen has so far come about equally as a by-product in the manufacture of coke and in the form of imported Chile saltpetre; and the latter will no longer be available, although the former may be increased and supplemented to some extent by means of calcium nitrite. In addition to these causes the agricultural production of East Prussia and Alsace-Lorraine has suffered, whilst it is not safe to reckon on a lasting out of stores in reserve. "We are as a people placed in the position of an individual who has up to now had a considerable income at command, and who learns by means of a sudden severe misfortune that with careful husbandry he can get on with much less."

Chapter III. deals with

The Food Requirements of the German People.

Section 1, on the *aim of nutrition*, gives a short sketch of the function of the human organism as a machine, distinguishing between the food-supply required to produce the running energy and that to make up for loss of substance. For the latter purpose and only for this is proteid required. Sufficient proteid must be supplied to make up for the regular loss, but not more than this, as fat and carbohydrate are precisely of the same value as producers of energy. 1 gramme of fat produces 9·3 calories, 1 gramme carbohydrate or proteid produces 4·1 calories; and Rubner's work makes it certain that from the point of view of energy-production it is quite immaterial whether the body uses one or other of these sources of supply. If, therefore, there are public grounds for reducing the consumption of proteid this can be done without concern so long as the hygienic proteid-minimum is retained. This quantity is a relatively constant one, whereas the requirement in energy-producers varies largely according to the mechanical energy of the subject.

2. *The requirement in calories* of the German people for a year must be determined. This should be expressed in net calories, allowing for the fact that proteid is excreted incompletely metabolised, whereas fats and carbohydrates burn without waste, and allowing further for the incomplete utilisation of substances of difficult digestion. The energy requirement of the organism depends on the work which it has to do and the warmth which it must produce, further to some extent on the temperament of each subject. Carl von Voit's basis for a man of 70 kilogrammes weight on a mixed diet gave 3050 calories for moderate work and 3575 calories for heavy work. Rubner's figures vary from 2445 to 6109 calories, and the average figure of 3000 may be taken as not

¹ Die Deutsche Volksernährung und der Englische Aushungerungsplan. Eine Denkschrift von Friedrich Aereboe, Karl Ballod, Franz Beysschlag, Wilhelm Caspari, Paul Eltzbacher, Hedwig Heyl, Paul Krusch, Robert Kuczyński, Kurt Lehmann, Otto Lemmermann, Karl Oppenheimer, Max Rubner, Kurt von Rümker, Bruno Tacke, Hermann Warmbold, und Nathan Zuntz. Herausgegeben von Paul Eltzbacher. (Friedr. Vieweg und Sohn, Braunschweig, 1914.)

too low. The influence of age and sex must also be considered. The requirements of the adult woman can be based on the lower male standard of work. Engel, Rubner, Atwater, and Zuntz have given tables for each year of life, the simplest being the new table of Zuntz, in which 40 per cent. is reckoned for age 2-4, 50 per cent. for age 5-9, 75 per cent. for age 10-14 years, from then on 100 per cent. for a male and 80 per cent. for a female, with a drop to 90 per cent. for the male after 60 years. Worked out on the basis of the German census of Jan. 1st, 1911, with a total population of 64,992,238 persons, an average of the various scales gives 49,543,889 units, which must be increased by 4·6 per cent. on account of the increase of population to the present year, giving 51,822,908 units. The calculation, 3000 calories $\times$ 365 $\times$ 51,822,908 = 56·75 billion calories, gives the total requirement of the German people for a whole year of the war.

3. The *proteid requirement* must be separately estimated, as it forms the building material of the body and cannot be replaced by any other foodstuff. Its complicated molecule contains not only carbon, hydrogen, and oxygen, but also invariably nitrogen and sulphur, in many cases phosphorus, and often iron and other elements. As the nitrogen content varies only within narrow limits, this can be used as a guide and the nitrogen balance of the body worked out. With an excessive intake of proteid nitrogen is at first stored up, but soon excretion again equals intake. The smallest intake of proteid with which the nitrogen balance can be maintained is known as the physiological proteid minimum. This may be as low as 17 grammes, but probably the organism comes thereby to harm in the long run. The hygienic proteid minimum is the quantity necessary to maintain the body in perfect condition and energy. This quantity varies within fairly wide limits with the kind of proteid and the composition of the rest of the food. The chief influence is exerted by the body weight. Voit held that for a body weight of 70 kilos, 105 grammes of proteid were necessary daily. This value was intentionally chosen high to allow of a certain margin, and, as Rubner pointed out, was taken from the statistical material of Munich, in which the consumption of meat is very large. Neumann in 1902 arrived at a value of 71 grammes; Schumburg in 1893 at an average value of 60 grammes; but as average values for all ranks of society on the usual mixed diet are being considered, it will be wise to allow for 70 grammes of proteid for an active man requiring 3000 calories of total energy. 70 grammes of proteid have a value of 287 calories, and therefore amount to 9·6 per cent. of the total food. On a vegetable diet this is easily possible, for potatoes contain only 7·1 per cent.; rice, 7·3 per cent.; rye bread, 8·7 per cent. of proteid. But for foods of animal origin a higher percentage of 15 per cent. to 16 per cent. of proteid must generally be reckoned. Hence, for the basis of this calculation it is assumed that the adult man takes 11 per cent. of his total calories in the form of proteid. For an average man of 3000 calories this gives 330 calories in the form of proteid, and therewith a daily requirement of 80 grammes of proteid; and in view of the fact of the varied diet of the population of town and country this is not too high a figure to take. The requirement of the adult woman may be put at 15 per cent. less, or 68 grammes; that of the child is 40 grammes for the first to the sixth year, 50 grammes for the seventh to the twelfth year, and 65 grammes for the thirteenth to the eighteenth year. Calculating now on the basis of the total population from the census of Jan. 1st, 1911, the total daily requirement of proteid is 4203 tons; and allowing as before for an increase of population by 4·6 per cent. up to the outbreak of the war, the yearly requirement of the German people works out at 4396 tons $\times$ 365 = 1,605,000 tons of proteid.

Chapter IV. treats of

The Actual Consumption of Food by the German People before the War.

In order to do this (1) the foodstuffs produced in Germany and used by man, and (2) the excess of import over export in such foodstuffs are determined. In order to determine further what part of the consumption is directly or indirectly from abroad it is necessary to add to the excess of imports in foodstuffs, the excess also in the importation of materials used in the raising of home produce. The consumption of meat, for instance, is given by the sum of beasts slaughtered in the country and the excess of import over export. But the

proportion of this consumption due to the foreigner is obtained by the excess of imports in (1) meat, (2) live cattle, and (3) fodder used for feeding home cattle, all three expressed in terms of meat. The chapter ends with two tables, one giving the total consumption of foodstuffs for the average of the year 1912-13, and the same worked out in terms of daily consumption per head. These tables appear on the opposite page.

Under each heading a wealth of interesting detail is given. Thus of 11.9 million tons of home-grown rye, 1.1 million tons are reserved for seed corn and 2.7 million used for feeding cattle and for industrial purposes, leaving 8.1 million for human food, whilst half a million is exported. Of the 4.5 million tons of home-grown wheat on the other hand only 0.4 million is used for fodder and 0.3 for seed corn, while 3.8 remain for human use, and in addition 2 millions are imported. Other enormous items in the import list are 2.9 million tons of barley and 1 million tons of maize. On the whole group 14 per cent. of the proteid and 10 per cent. of the total calories required are at present imported. Fruit trees in the German Empire amount to 61 million apples, 29 million pears, 81 million plums, and 25 million cherries, of which the yield is estimated at 28, 16, 3, and 9 kilogrammes per tree respectively. Of sugar the home production amounts to 1.9 million tons, while 0.6 million is exported, so that something like 50 per cent. more sugar is produced in the country than is required. Under the heading of meat the number of beasts slaughtered amounts to: of swine 23.8 millions, calves 43, sheep 2.7, and cows 1.7, the amount of pork being, therefore, nearly five times that of any other meat. Of other creatures one notes 171,000 horses, 8000 dogs, 6 million tame rabbits, 13 million geese, and 80 million fowls, ducks, and pigeons. Reckoning imported barley in terms of pig-flesh it is estimated that 0.6 out of 2.6 million tons of pork are owing abroad as well as a very large quantity of imported animal fat. Of fish, as large a proportion as 64 per cent. of the total proteid and 71 per cent. of the total calories is imported. Of milk products 136,000 tons more are imported than are exported, largely in the form of butter and cream; also to a smaller extent cheese and milk. Enormous quantities also of cattle fodder are imported, including 2 million tons of bran and half a million ton of oil-cake. For calculating the proteid content of this, as utilised in the milk produced from them, 664,000 tons of raw proteid are estimated to account for 9.5 million tons of milk, and the final result gives 65 per cent. of proteid and 38 per cent. of total calories of milk products are imported. In eggs, a census of hens and turkeys is available, and the assumption made that a hen lays on an average 70 eggs in the year, weighing 50 grammes each, giving a total production of 257,000 tons of eggs. In spite of this, 41 per cent. of the proteid of eggs comes from abroad.

Chapter V. considers the question of

The Deficit and How to Cover it.

1. It is first necessary to determine the size of the deficit during the war, allowing on the one hand for the exclusion of foreign products, and on the other for some diminution of home production during the war. In a double sense must the deficit be considered in comparison with previous consumption as well as with actual physiological necessity. On the basis of the consumption of the years 1912-13, and allowing for the increase of population, the consumption during the war on present lines would amount to 90.42 billion calories with 2307 million tons of proteid. On the other hand, the actual physiological requirements for 68 million Germans works out at 56.75 billion calories and 1605 thousand tons of proteid. This means that our consumption exceeds our actual need by 59 per cent. of nutritive value and 44 per cent. of actual proteid. These figures are at first sight very surprising, especially in view of the careful statistics on which they are based. But the causes of the discrepancy are discoverable. To a certain extent the difference is inevitable even with extreme economy, as losses are unavoidable, especially when foodstuffs pass through many hands. But far greater than this is the unnecessary elevation of the consumption beyond actual need occurring in the houses of well-to-do people and due to actual waste of foodstuffs. The actual consumption exceeds the physiological requirement more in total calories than in proteids, and it may therefore be guessed that fats and carbohydrates are wasted more than proteid. These are in part more liable to spoil, especially as on account of their cheapness less care is bestowed on them. Potatoes, vegetables,

fruit, and fat are lost in enormous quantities on the way to the consumer, whereas grains are more permanent and more care is taken to keep meat and milk fresh. In order to reckon our deficit we must determine what amount of foodstuffs we should be in a position to consume on the basis of our own production without importing from abroad, and of course without export. On the average of the years 1912-13 we have produced at home 71.24 billion calories and 1636 thousand tons of proteid. Home produce is likely to have increased since then up to the commencement of the war, but in order to be on the safe side we have reckoned with a diminution rather than an increase, bearing in mind that the next harvests will probably diminish on account of lack of trained labour, horses, and manures. Other sources may also be shorter during the war, as, for instance, the North Sea fishery. And in East Prussia and Alsace-Lorraine stores have been destroyed and removed and production lessened. Full account is taken of this by assuming a diminution of 5 per cent., when the figures stand as follows:—

Nutritive values.	Calories in billions.	Proteid in thousand tons.
Requirement	56.75	1605
Actual Consumption	90.42	2307
Available on continuance of existing conditions	67.68	1554

From this we see that if continued on present lines our economy will show a deficit of 25 per cent. of total foodstuffs and of 33 per cent. of proteid on what we have hitherto consumed. The position is more favourable if we consider actual physiological requirements when we have 19 per cent. more total food than we required and 3 per cent. too little proteid. The cause of the less favourable character of the second item is the complete falling out of foreign fodder for the production of such proteid-rich foods as meat or milk, whereas home-grown sugar is available in its entirety. With every day of continuance on present lines our deficit is increasing, and if no change is made for six months the deficit of available proteid for the following six months will be increased to 50 per cent. "This is the seriousness of the position." To cover the deficit in calories is a relatively simple task. To cover the deficit in proteid is a much more difficult one. Effort must be made to supply the lacking 3 per cent., and with an additional margin for the losses occurring between producer and consumer. "We can cover our deficiency," but certainly not in the sense of being in a position to consume the same quantities as before the war, but to more than cover the physiological need. "The means to do this is an alteration of our economical life in accordance with the situation created by the war." We have had success in limiting out travelling requirement to that of our forefathers, and can certainly do the same for our food requirements, becoming also in so doing more healthy. Any personal interest must be subservient to the good of the community, and the plea of the sugar industry for special treatment is not valid, as in such a time no money need be earned, but the nation must be fed. The problem requires treatment as a whole and on broad principles.

2. *Storage.*—Before the outbreak of the war Ballod had proposed the formation of State grain stores in which large quantities of corn were to be stored up against the outbreak of war. This was unfortunately not done, but at all events the quantities of grain and pulses required for spring sowing must be saved, and at the same time pork must be preserved in large quantities as the slaughtering of pigs is now inevitable, and the present glut would otherwise be followed by a later scarcity. At the same time the largest possible amount of foodstuffs should be obtained from neutral countries, as well as seed, manure, and fuel for motors. The guiding principles should be high nutritive value and small storage room. The prohibition of export of foodstuffs must be made absolute and sugar no longer exported, even though it should not reach England. No consideration for friendly relations with neutral countries should interfere with this most necessary condition.

3. *Adaptation of production.*—The essential point is the nutritive and especially proteid value of what is produced, and farmers must subordinate their personal interest to that of the community. Ground must be reserved for those vegetables which afford a large quantity of nutriment, such as beet and potatoes. The necessary seed for producing summer crops of grain and fodder must be provided, and the

difficulties owing to lack of labour and of manure surmounted in every possible way, whilst the culture of moors and of areas not at present available for agriculture must be taken in hand. Cattle must be fed with fodder at present too little considered, such as beech nuts, acorns, and green stuff, and every waste of fodder must be carefully avoided. The cost is a secondary matter, and the State must see that the necessary steam and motor ploughs are manufactured as well as the needful nitrogenous manures. Garden and wild fruits must be carefully stored. Foodstuffs must no longer be used for technical purposes—e.g., starch and spirit from grain and potatoes, soap from fats—except in so far as this cannot be avoided. The grain and potatoes used for feeding cattle have a far higher value if employed directly for the nourishment of man. "With the milk, corn, grain, and potatoes which a pig consumes, double as many human beings can be nourished as with the resulting pork." The experiments of Zuntz, Kellner, and other have shown that more than 50 per cent. of the calories are always lost by passage of foodstuffs through an animal. For the same reason the production of butter is to be restricted, and finally, careful attention paid to storage and preservation, especially of vegetables in the winter and of fruit in the form of jams and preserves.

4. *Adaptation of habits of life.*—The third and last method of covering the deficit is alteration of habits of life, and this need by no means be a radical one. Small alterations will suffice. Less meat and fat must be used than in the last few decades, but an exclusively vegetable diet is not necessary, and even vegetable foods may be limited without harm. Just at present an excess of pork is available, but as we have seen this should be preserved and not immediately consumed. In individual households the avoidance of loss and waste is imperative. Rubner calculated in Berlin that daily 20 grammes of fat are wasted in the effluent for each head of the population. Apart from economical use of food other points have to be considered. Starch should not be used for clothing, and coke is to be employed in preference to coal in order to make available the necessary ammonia for manure.

5. *The carrying out of the necessary measures.*—Three methods will be required: new laws, careful administration, and instruction of the people. The edict of August 4th, 1914, empowered the Bundesrat to enact all necessary economic measures. Maximum prices may be fixed where, as in the case of sugar, it is desirable to encourage a large consumption; minimum prices where, as in the case of meat, storage is preferable to immediate use. Regulation of prices is especially desirable where the use of one article is preferable to that of another—e.g., the abundant rye in preference to the limited wheat. Local authorities can buy up and store the present glut of pork; ensure a sufficiency of seed grain for the spring; and erect installations for drying potatoes and producing nitrogenous manure from the air. The most important measure remains—the instruction of the populace, which can be done through the agricultural societies, the trades unions, the national service of women, as well as through the press. If all these means are employed the English starvation plan will certainly be brought to naught.

Chapter VI. deals with

The Prohibition of Exports.

Three Royal edicts were already enacted on July 31st, 1914, dealing with foodstuffs, animals, animal products, and certain raw materials, the carrying out being left to the Chancellor. Certain exceptions have since been made which are not without importance.

1. *Grain.*—It is much to be regretted that our Government in friendly consideration for Switzerland allowed 2500 wagons of grain to be exported; but if this is done for Switzerland it may be a cause of complaint that similar consideration is not shown to other neighbouring neutral States. Switzerland as a small neutral country is also in the position to obtain its supply of grain through Italy. Denmark has not hesitated to prohibit the export of barley to Germany, and no political consideration can justify any relaxation with regard to our vital interests.

2. *Sugar.*—It is especially important that no sugar should be exported. The sugar industry obtained from the Government a relaxation of the prohibition in the sense that export should be permitted, deciding from case to case up to the amount exported in the year 1913—viz., 1.1 million tons.

But no consideration for the financial circumstances of a particular industry should result in our sending useful food out of the country. Rather the people should be encouraged to increase their consumption, which would use up the available supply if it reached the American count of 36 kilos. per head of population, and this is less than the English figure of 40 kilos. In 1904, when the price of syrup sank 29 per cent., the consumption of sugar increased rather more than correspondingly—by 34 per cent., in fact. This increased consumption of sugar can then partly make up for the shortage of fat. This consideration alone should suffice, but as a matter of fact of the 1.1 million tons 0.8 went to England, whether directly or indirectly, through neutral countries. The keeping up of the level of German exchange in neutral markets is a matter of entirely subsidiary importance. In consideration of all this the Government has already agreed to withdraw part of the concession from the sugar industry.

Chapter VII. is concerned with matters relating to

Agriculture.

1. *The crops to be chosen.*—The necessity is clear; we must not allow the deficit due to failing imports to be increased by lack of production. On the contrary, we must increase the home crops, and as far as possible such crops as yield a high proportion of proteid food. In this respect the pulses are almost equal to meat. On the average of the years 1912-13 we imported 251,000 tons peas, 31,000 tons beans, and 28,000 tons lentils, and the farmer should attempt to produce these at home, naturally with some care, as these crops are more dependent on local conditions than others. It has further been proposed to let the place of potatoes and beet to some extent be taken by the culture of corn. Imported wheat to the extent of 2,000,000 tons has fallen out, and although this may to some extent be replaced by the 600,000 tons of rye which we no longer export, a deficit still remains which might be made good with the 1,100,000 tons of beet sugar which have been hitherto exported. But the suggestion is inadvisable on two grounds: firstly, the beet and potatoes yield far more per unit of area than corn, both in value and in foodstuffs, and they deplete the soil far less in respect of nitrogenous constituents. They afford, too, fodder for more and better cattle, which in their turn yield more and better manure for the land. And secondly, the intensive culture of these crops exerts a much healthier influence on the agricultural industry in general, on the breeding of heavier horses and stronger oxen, on the manufacture of agricultural implements, and has produced an enormous increase in freight on canals and railways, thereby assisting in high degree the finances of the State.

2. *Seed corn.*—It is of the utmost importance that sufficient seed corn should be available for the spring sowing. First of all for summer grain. The limitation of available labour has in many places hindered the sowing of the winter crop, especially in East Prussia and Alsace-Lorraine, and consequently the summer crop must be largely increased. Where an oat crop is doubtful barley can be used to take the place of the imported barley for fodder. In all cases the right sort of grain must be carefully chosen in advance. Of pulses there is a risk that the available stock may all be used up by the spring. Similarly clover and grass seed must be obtained, and all this can only be done by the organisation of the State itself.

3. *Labour and traction.*—The lack of labour for the harvest has made itself less felt in the autumn than was feared. The superfluous industrial workers will gradually filter into agricultural channels, and the great number of prisoners of war—now much over half a million—will provide many well-trained agricultural labourers. The lack of beasts for traction is not so great as might appear at first sight. Some half a million horses have been claimed by the army and the import of some 130,000 horses has stopped. Since the total number is somewhat more than four and a half millions, this means a reduction of some 14 per cent. But the earlier breaking-in of the foals has already almost compensated for this, and not only oxen and bulls, but also cows, can be trained for ploughing without harm if their diet is increased by so much beet and potatoes. Steam and motor ploughs can be used more than is the case at present, and the greater landowners must lend them to the smaller ones in their neighbourhood. The hundreds of motor ploughs stored in the manufactories must also be put into use. For

steam and electrically driven ploughs there will be no lack of power; for the motors the supply of petrol may be replaced by benzol, which is a by-product in the manufacture of coke. The latter should be used as fuel, not only in the household economy, but also in the locomotive, and the price reduced to this end. Spirit was used extensively for motors during the first months of the war and may continue to be so used with the addition of a moderate quantity of benzol. Comparing the consumption of foodstuffs required to produce the alcohol for motors with that of oxen for traction the figures work out as 391 kilogrammes of starch for 28 oxen per day and 300 kilogrammes of spirit for a motor plough per day. The advantage rests, therefore, with the plough, which further only requires two hands, whereas 28 oxen necessitate at least seven labourers. The motor plough is essential in places where there is a lack of beasts.

4. *Manures*.—In order to produce a good yield sufficient manure is essential. Much more attention should be given to the storing of manure in order that the available nitrogen should not be lost. Various calculations have been made that the usual loss is some 30 per cent., or a yearly waste of at least 600 million marks (= £30,000,000) for the whole of Germany. The money value of this loss is some five or six times as great as that of imported saltpetre, and is about equal to the sum which German agriculture pays altogether for artificial manures. Little or nothing can be done with the various chemical preservatives, but since the loss is due to the activity of micro-organisms, and most of these require atmospheric oxygen, it can be prevented by avoiding access of air and keeping the dung firm and moist. Even so a loss of some 13 per cent. occurs. By covering with peat it can be still further reduced to 7 per cent., and a similar saving is effected by keeping the solid and fluid parts of the dung separate according to Soxhlet's method. Not less importance is due to the artificial manures. To them is largely owing the rise of our agriculture. In the last 30 years our harvests of grain and potatoes have kept pace with the increase of population. This has, in the first place, been due to the introduction and use of artificial manures; secondly, to the better results of plant breeding, the better working up of the soil with manure, the keeping down of plant disease, &c. It has been estimated that of these various factors the artificial manure is responsible for 50 per cent., more fruitful kinds of seed for 30 per cent., and other measures for 20 per cent. of the advantages gained. Four substances have to be considered: nitrogen, phosphoric acid, potash, and chalk, of which only the first three offer any difficulties to produce. Amongst them nitrogen is vastly the most important. A series of important experiments in various parts of the country by Hansen, Schultze, and Lemmermann have shown that without the nitrogenous element all other manure is of very little avail. In Germany potash is present in abundance, and only the difficulty of freight may hinder its sufficient use. The State must come to our aid by reduction of freight rates, and will be later on compensated by the increased freights for the crops themselves. The supply of phosphoric acid depends on the Thomas-slag, which is itself dependent on the iron industry and the needs of the army. To produce the superphosphates the supply of crude phosphate may be supplemented from Belgium, where such beds are present in the provinces of Liège and Hennegau. The necessary sulphuric acid to work up the crude phosphate into superphosphate has been much reduced by the loss of the imported pyrites. There are beds of sulphur-containing rock in Germany—for instance, at Goslar—the working of which would supply the necessary sulphur. In spite of everything that can be done there will still be a certain diminution in the supply of phosphoric acid, which should, however, not make itself perceptibly felt at present in view of excess of supply in the last few years. Immensely more important is the obtaining of sufficient nitrogen. It has been calculated that 8,000,000 double centners (a double centner = 100 kilos.) of nitrogenous salts less than usual are available, and that for each nitrogen unit lacking, $3\frac{1}{2}$ to 4 units less of grain will be produced by the fields. Thus an amount of 28–32 million double-centners less corn will be produced—i.e., about one-fifth of the total harvest. In 1913 more than half a million tons of Chile saltpetre were used as manure. The place of this can be taken by applying the nitrogen of the air with the aid of arc lamps, but the quantity so far has been minimal—38,000 tons in 1913. Next to saltpetre the most

important manure is ammonium sulphate, occurring in large quantities as a by-product in the distillation of coal. Its nitrogen content exceeded that of Chile saltpetre in the year 1913, and the quantity has increased since. Lastly, calcium nitride is produced by the action of nitrogen on calcium carbide, and this production increases from year to year. As along with the Chile saltpetre about one-half the available nitrogen has fallen out, the other sources must be stimulated to the utmost extent. The great electrical works of Germany possessed in 1913 some two million horse power, of which on the average only 18·8 per cent. were used. Technically it would be possible to produce enough calcium nitride by means of this power without interfering with the ordinary supply of electricity. The State must take this important matter in hand.

5. *Culture of moors*.—According to Fleischer we possess in Germany about 20,000 square kilometres of unused moor land which can easily be brought to useful cultivation by the addition of suitable manures. Half of this area probably requires only a supply of potash and phosphoric acid, possessing already sufficient nitrogen. Especially the Russian prisoners of war are agricultural labourers and could carry out this useful work to great advantage. When one considers that the hektar (1 hektar = $2\frac{1}{2}$ acres) of improved moor yields a certain harvest of some 20–30 double-centners of rye or oats, or 180–220 double-centners of potatoes, or 50–60 double centners of valuable hay, or on grazing on 3–4 double-centners of living cattle, the value of this work may well be seen. The latest experiments have shown that vegetables especially flourish on such a soil, especially with hand spadework, which is available in sufficient quantity with the help of the prisoners of war and the out-of-works. The stretch of country on each side of the Hamburg-Bremen Railway is particularly suitable. Further increase of harvests could be attained by extending the area of sewage works in the neighbourhood of large towns. These are mostly far too small and suffer from excess of effluents. Finally, an increase in agricultural production could be attained by dividing up large tracts amongst peasant proprietors, who would then carry out more intensive culture of the smaller areas. In this direction also, when the war has carried off so many owners of large properties, or made it impossible for them to conduct them further, the State must intervene.

Chapter VIII. deals with questions relating to

Live Stock.

1. *The reduction in the number of pigs and milch cows*.—“One thing must under all circumstances be done—reduce the number of beasts.” A great quantity of imported fodder is lacking, especially barley, maize, bran, and oil-cake. So far these have partly been used for feeding pigs, partly for increasing the yield of cows' milk beyond what could be attained with home fodder. We should only add to our deficit if we were to replace this fodder with material such as corn, which could be used directly for human food, for, passed through an animal, more than half the nutritive value is lost. In addition we are obliged to deprive the cattle of some of the foodstuffs suitable for human food with which they have hitherto been fed. The Government has therefore forbidden under penalty the use of bread corn as fodder, amounting in rye alone to 2,000,000 tons yearly. We must in future divide the available fodder among a smaller number of beasts, for it is in general more advantageous to feed a small number abundantly than a larger number sparingly. The mere limitation of the number amongst which a given amount of fodder is divided makes it possible to produce more human food for the same consumption of fodder, and therewith further limiting our deficit. The necessary reduction of the number of beasts demands, on the one hand, a slaughtering of a certain proportion, and on the other a limitation in the production and breeding. It will be readily understood that the thought of such a reduction will be very sore to the heart of many of the farmers who have attained a large stock with years of hard labour, but there is no place for sentiment in the present fight for existence. Only we must see to it that the diminution does not damage the future of the industry, and that on the return of peace the breeding can be resumed in the necessary intensity. These questions are not simple of solution, the first being in what kind of animal the diminution shall be made. Here two points must be considered, the first concerning the kind of fodder. In general the reduction should be made among the

beasts who consume fodder which could directly serve for the food of man. The pig is the greatest food competitor of man. The second point concerns the best employment of the fodder. We should rather destroy such beasts as do not put the fodder to an economical use. In this respect the varying production of meat and milk is of special interest. The experiments of Kellner and König have led to the following results. In the feeding of a pig of 15 kilos. up to a weight of 120 kilos. 24 per cent. of proteid and 44 per cent. of total food value is retained for the nutrition of man. On the other hand, in rearing a calf from 30 kilos. up to a weight of 360 kilos. only 20 per cent. of proteid and 14 per cent. of total food value is available. A milch cow weighing 500 kilos. and giving in the year 2200 litres of milk gives back to man 36 per cent. of the proteid and 24 per cent. of the total food value with which it is supplied. The different value of the products must also be considered. With milk at 20 pf. (= nearly 2½d.) the litre and pork at 2 marks (or shillings) a kilo., we pay for 100 grammes of proteid 57 pf. in the case of milk and 1 mark in the case of pork; and apart from proteid the milk contains far more nutriment than the pork. In proteid economy, therefore, the milch cow is far to be preferred to the pig or the calf. Hence the cow should be retained as far as possible and only the wasteful feeders destroyed. If the question of the economical employment of fodder were the only one, then the bullocks should principally be destroyed. But since the kind of fodder is of still greater importance the limitation of pigs is the first to be undertaken.

2. *The degree of the limitation of the number of beasts.*—The reasons making the limitation necessary are the lack of imported fodder and the prohibition of the employment of bread corn. Both necessitate a diminution, since it would be indefensible to maintain the present number with insufficient and therefore unproductive feeding. Two methods are available to determine the necessary reduction. In considering the measures for the whole country the calculation can best be made from the quantity of fodder which is no longer available, whereas for any particular district or farm the calculation must of necessity be made on the actual figures of fodder still available. First, then, let us consider in what degree in general the number of cattle must be reduced. The missing fodder was principally used for two purposes: for the feeding of pigs and the keeping of milch cows. Roughly, we may assume that barley and maize were given to the pigs and the other fodder to the cows. On this basis we may reckon that pigs were fattened on the excess of imported barley and maize as far as this served for fodder at all. On the average of 1912-13 2.9 million tons were available with a proteid content of 240,000 tons. To see how many pigs this amount could have fattened it is not possible to calculate simply from the physiological fact that a pig in order to increase from 15 to 120 kilos. in nine months requires fodder of 1.4 million calories, equivalent to 493 kilos. of barley or 411 kilos. of maize; for this calculation does not allow for loss on transport and storing, for waste in feeding, for digestive disturbances and disease, and death during fattening. It is better to reckon as the practical farmer does that a pig puts on a kilo. of weight for 5 kilos. of corn (5½ kilos. of barley and correspondingly less of maize). If the fattening of a pig is expressed in this way in corn value, 525 kilos. (or 575 kilos. of barley) would be necessary, giving roughly 5½ millions of fattened pigs, or somewhat more than a fifth of the last census. The reduction should specially be made in the pig-fattening establishments of the province of Hanover. For milk production we should have—on our basis of calculation—to allow for the lack of import of fodder, as well as the home rye which is no longer available for animals. The import reckoned in proteid value amounted in 1912-13 to 664,000 tons, the home-grown rye to 192,000, of which only the bran (some 50,000) is now available. The total deficit for milk production is therefore 806,000 tons of proteid. Now, a cow gives on an average 2200 litres of milk in the year, and requires as fodder for its own needs on the usual calculation 350 grammes daily, or 128 kilos. yearly, of proteid, and in addition as fodder for the production of milk 70 grammes for each litre, or 154 kilos. in the year. Adding these together, each cow requires 282 kilos. proteid per year. 806,000 tons of proteid content in the rye no longer available would have served to feed 2.86 millions of milch cows, or

some 27 per cent. of the whole head of cattle. This calculation, however, gives only a provisional picture, for the entirely incorrect assumption has been made that farming methods would continue as heretofore. This must not be allowed to occur. Fodder must be economised and new sources utilised; suitable additional fodder plants are to be cultivated, useless cattle got rid of, the waste of raw fodder avoided, and the cattle treated according to their individual needs. It has been calculated that with economy of the use of fodder in every possible direction a saving might be effected, so that only 2 million cows need be got rid of. But this is without allowing for a limitation in the keeping of pigs, and, as we have seen, the proteid of fodder is obtained in almost twice the quantity in milk that it is in the production of pork. For every three and a half pigs destroyed one cow may be retained, and we may accordingly compromise by reducing the number of pigs by 9 millions, the milch cows by only 1 million, respectively 35 per cent. and 10 per cent. of the whole.

3. *The carrying out of the reduction.*—In different parts of the country different conditions as regards fodder prevail. In any case those cows should be slaughtered in which the milk production is less advantageous, and even then not all at the same time, to avoid a temporary excess of meat at a low price and an eventual meat famine. The State should here again step in to buy and preserve the surplus meat, and a minimum price should also be fixed. As regards the production of pigs, so long as the skim and butter-milk cannot be otherwise employed they should be retained, and for the present the potato harvest cannot be otherwise utilised, especially since the slaughter will be a successive one and the feeding of young pigs must in any case not be too scanty in order that they may remain capable of adequate fattening.

4. *Small livestock.*—The proposal has been made to extend as far as possible the keeping of fowls and rabbits, thereby producing a more varied and agreeable diet, which would be of practical importance with foreign production entirely cut off. But although for years fowl-keeping has been encouraged, in the first half of the present year over 106 million marks' worth of eggs were imported into Germany, and this condition is hardly likely to alter rapidly. The rearing of chickens also involves foodstuffs which might serve directly for human consumption, and the question is in fact only a practical one where the fowls can run free in the farm and on the fields and feed on insects, worms, plants, &c., which otherwise would remain unused. The amount of care and attention required would often be prohibitive, especially when so large a proportion of the population is on military service. But wherever possible the keeping of fowls should be borne in mind.

5. *Increased production of fodder.*—The leaves of beet and potatoes if carefully harvested and preserved afford useful fodder, and a great part of the green stuff which is usually ploughed in may also be used as well as crops grown in the between-time of the principal crops, such as Chinese radish, white mustard, peas, &c. These measures were already recommended at the beginning of the war by the Agricultural Society and by experienced farmers.

Chapter IX. deals with

The Proper Utilisation of Agricultural Products.

1. *Corn and potatoes.*—Much can be done to cover our deficit by employing grain and potatoes to proper advantage. They belong together because they are commonly employed for the same purpose, whether for human nourishment, fodder, preparation of starch, or brewing. At present both are largely employed for feeding domestic animals, and this is not so questionable in the case of potatoes, of which we have a large excess. Of grain hitherto, not merely the residual grain—i.e., the part cast aside with the impurities on sifting—has been employed, but also some proportion impossible to estimate even of good grain among the smaller farmers. Such grain, employed indirectly for human nourishment through an animal, loses at least 50 per cent. of its food value. 1.4 million tons of corn are lacking, and in these circumstances the use for fodder must be limited to a minimum. The Government indeed on Oct. 28th, 1914, forbade its use on principle. "For every farmer it must be a matter of honour to observe this prohibition in the interest of the protection of his country." Fortunately a substitute can be found. More potatoes can be used, especially when by means of potato-drying large

quantities are preserved from rotting. Beet parings can also be used. These substitutes can gradually take the place of the usual rye.

Considerable quantities of grain and potatoes are lost for human food by their use in trade. Even if the substitutes produced are used for food a certain loss is inevitable—in the processes of starch-making and brewing—apart from the starch and spirit which are used for trade purposes. These uses must be carefully inspected. Starch is partly used in the kitchen for baking, partly for technical purposes, and is produced both from grain and potatoes. In the year 1911, 34,000 tons of rice, 25,000 tons of maize, and 23,000 tons of wheat flour were used. The two former are no longer available; hence there is a risk of wheat flour being used in their place. In preparing starch from corn the proteid content is lost, or has at all events not yet found adequate employment (so-called aleuronat has had no great success). For all purposes, whether of food or industry, wheat starch may be replaced by potato starch, which has the great advantage of not wasting any large proteid content. In 1910-11, 1.3 million tons of potatoes were used for starch, with the obvious advantage of producing a foodstuff capable of indefinite keeping, bearing in mind that the best form of preserving potatoes—viz., drying—is not possible for the whole quantity. The production of potato starch, if it is used for human food, is therefore free from drawback. If used for bread the proteid content of the latter will be diminished, and its place must be taken by adding skim milk. Zuntz and Magnus Levy have shown that such bread is well digested. Technical application of starch, on the other hand, must be limited. The employment for linen has no real use, and some ingenious person should discover a substitute for paperhanger's paste.

For the production of alcohol both grain and potatoes are used. In the years 1912-13, 3,000,000 tons of alcohol were manufactured. About half is drunk; the other half is used for various technical purposes. 89,000 tons of rye were used in the production of malt spirit. This employment is highly questionable, and the production of spirit from corn should be entirely forbidden. Of potatoes in the years 1912-13, 2.7 million tons were used in the distilleries. Against the use of potato spirit as a beverage the reduction of food value is not as great as might be supposed. 60 per cent. of the energy remains in the form of alcohol, 3 per cent. is lost in the vital process of the yeast, and the remaining 37 per cent. forms a useful fodder, of which in its turn one-third is later available in the form of meat and fat. Potatoes used directly for cooking as a rule lose 15 per cent. in peeling and 2 per cent. in imperfect digestion. Hence, *quâ* food value there is not much against the distillery. But in spite of this the use of alcohol should be limited as much as possible, as it is a poison and a danger to the health of the individual as well as to that of the community. Other considerations affect the part of the alcohol used for technical purposes. It is entirely lost as food, with the exception of the small residue for fodder. The use of alcohol for motor driving is an evil which cannot be altogether avoided, although it should be limited as far as possible. As an illuminant gas, acetylene, or electricity must take its place. Its use to replace benzine and petroleum is, to some extent, unavoidable, and any reduction in the production of alcohol from potatoes can hardly be expected. For brewing grain alone is employed, and in the form of beer our population enjoys more alcohol than in the form of spirit. In the years 1912-13 3.5 kilos. of alcohol yearly per head of population were consumed in the form of beer, and 2.2 kilos. in the form of spirit. Some 1.7 million tons of barley served for this purpose, and the question whether limitation is desirable is affected by the fact that barley ordinarily is very little used for human food. In brewing the nutritive value is fairly well maintained and an average loss of 12 per cent. may be reckoned with in malting and a further loss of 25 per cent. in extracting from the malt is compensated by the value of the remainder as fodder. A further 2 per cent. is lost in the vital process of the yeast, which itself, however, serves a useful purpose in baking. Hence, some 60 per cent. of the energy of the barley is retained for man in beer. Even in the production of pearl barley some 40 per cent. of food value is also lost.

The most important employment of grain is naturally the production of bread, and since the import of wheat

and the export of rye both have ceased it is necessary to mix rye flour with wheat, and an edict on Oct. 28th made an admixture of at least 10 per cent. of rye flour obligatory. To raise the price of wheat flour as a further inducement to saving would have the undesirable result of limiting the use of wheat flour to the well-to-do. The necessary regulation is gradually coming about and bakers should be encouraged to make the small rolls out of rye flour. The question is, further, of great importance whether the quantity of bread can be increased by a large addition of bran, bran being the part of the outer husk of corn separated in the grinding, and containing much proteid but in an indigestible cellulose envelope. Wholemeal contains the whole of the bran, the finest wheat flour about 60 per cent. of the total weight. Between these two extremes it is possible to manufacture a bread containing 70, 80, or 90 per cent. of the total weight. The separated bran, if employed for human consumption through an animal, loses at least 50 per cent. of its total value. On the other hand, if the whole of the bran is employed the resulting bread is not so perfectly digested—as, for instance, in the well-known pumpernickel. These considerations influenced the edict of Oct. 28th, according to which rye flour must contain at least 72 per cent. and wheat flour at least 75 per cent. of the total weight. The much-discussed question whether potato bread—i.e., bread with addition of potato flour—is advisable or not was settled also by the same edict, which prescribed an obligatory addition of 5 per cent. of potato flour to rye bread. A larger addition is permissible, but the bread must then bear the letter K (Kartoffel); if more than 20 per cent. the percentage must be stated on the bread. The production of potato bread is not necessitated by the lack of corn, but because grain is more easily stored than potatoes. On principle, however, it is doubtful whether the composition of a staple article of diet like bread should be altered after centuries of constant use, and when many people cover the whole of their proteid requirement in the form of bread. Potatoes contain less than one-fifth part of the proteid of rye flour. The addition of 5 per cent. is free from objection; more than 20 per cent. is inadvisable, especially as, according to Hellsten's experiments, digestion is then less perfect. Moderate saving of food value might be attained by dispensing with yeast. The alcohol and carbonic acid lost in the fermenting of the dough amounts to some 2 per cent. of the food value. But the employment of baking powder or of mechanical means is technically very difficult.

The complete utilisation of potatoes is endangered by the fact that a part of their food value is lost by rotting during long storage. In a year some 4 million tons are wasted in this way. Much may be done by correct storage, and latterly the practice of drying has helped considerably. In one form whole potatoes are cut into slices and dried in an oven, the resulting material being used for fodder. In a second, potatoes are steamed, freed of their peel, and pressed between rollers into thin discs. Although mostly used for pigs, they are then quite suitable as human food. A special advantage is the reduction in weight for transport to about one-quarter. Unfortunately the existing apparatus working continuously can only dry some 2½ million tons during the present winter.

2. *Vegetables, fruit.*—A not inconsiderable increase in our food-supply can be reached by better utilisation of vegetables and fruit. The edible fungi should not be wasted, and for vegetables four methods of keeping come into question: storage, pickling, drying, and preserving. Cabbages especially, instead of being sold almost for nothing in the autumn, should be stored in frost-free rooms which the local authorities and coöperative unions should provide. There is a larger field for the production of sauerkraut and the pickling of beetroots. The drying of vegetables is more complicated, but more might be done in this way as well as by sterilising in tins and glasses, which is, however, both expensive and complicated. Especially in individual households much can be done. The same applies to fruit. Home-grown garden fruits have by no means been used to full advantage, and there has specially been a lack of an organised market for windfalls and the cheaper kinds of fruit which have generally been given to pigs. The wild fruits—bilberries, blackberries, hips, elderberries, &c.—should not be imported but diligently collected in our own country, and a market organised for this purpose.

Preserving with sugar is most desirable, as in this way an increased employment of home-grown sugar would result. As an addition to a dish of cereals and potatoes they will serve greatly to limit the consumption of meat.

3. *Sugar*.—An attempt must be made to utilise properly the million or so tons of sugar which will no longer be exported. First and foremost is its employment to preserve fruit, and the transport tariff to the manufactories should be correspondingly reduced. It is clear that even after the war English markets for our sugar are by no means assured. The surplus may be employed as fodder, and especially to make palatable to the beasts forms of fodder which would not otherwise be so, especially the beet parings, and also straw, chaff, &c. The sugar would mostly be in the form of molasses, the residual non-crystallisable remains from the manufactory. Whole beetroot cannot in large quantity be given safely as fodder, and for 1000 kilos. of milch cow it is only advisable to feed some 10 kilos. of beet, for cattle 15 kilos., for horses 8 kilos., and for sheep 25 kilos. Their employment is safest for pigs, but their use should not then exceed 25 kilos. for 1000 kilos. of living weight, and it must be borne in mind that extra proteid must also be given. As beets are heavy they can only be given within short distances of where grown, and in any case the economy of the 300 odd sugar manufactories which employ a large number of workmen should not be seriously interfered with. In some factories already some 20 per cent. of the sugar is left in the peeling, which then forms a simple and economical fodder.

4. *Milk*.—Milk is a product which if carefully utilised, will form a considerable gain in our food-supply. Before the war annually some 20 milliard litres of cows' milk were produced, not allowing for what the calves themselves took. A reduction of 10 per cent. in the head of stock has been contemplated, with a corresponding reduction of about 18 milliard litres. At the present time two-fifths are used directly as full milk, a small part made into cheese, and more than half into butter. A considerable loss of food value occurs in the latter process. The whole content of carbohydrates and proteid goes into the skim and butter milk and the whole of the fat into butter. The figures for milk are roughly 3.5 per cent. fat, 3.2 per cent. proteid, 4.8 per cent. carbohydrate; and since the fat is double as rich in calories as the other constituents, the larger part of the energy-content is found in the butter. Nearly the whole of the body-building material is found in the skim milk. On present lines 8 or 9 milliard litres of skim milk are produced, and it is clear that this may have an enormous application in covering our proteid requirements. Unfortunately at present skim milk is only used in small proportion for home consumption. Its only large employment is to make skim cheese, whether curd or in more permanent form. A further proportion is used in margarine fabrication, where only a portion of its food value remains in the margarine, the rest going for pig fodder. As a drink both skim milk and butter milk are used very little, and in the raw state it is especially prone to carry tubercle bacilli and should only be used in a pasteurised or sterilised condition. But in cooking, where it might be largely employed, it is at present little in vogue. This is partly owing to the excessive consumption of meat and to ignorance on the part of the housewife of the use of skim milk, and also to its relatively high price. In consequence of this at present the skim milk is yearly to the extent of 5 milliard litres given to pigs, entailing, as we have seen, a reduction of at least 50 per cent. in its nutritive value. Careful instruction in its use should be given to housewives, the railway must assist by low tariff, and the price fixed at less than one-half of that of full milk. Further propaganda should be made for the larger employment of cheese both taken alone and as an addition to other foods, thereby saving the consumption of meat. But the third and most efficient means for preventing the loss of nutritive value, at present due to skim milk, is the limiting of the production of cream and butter corresponding at least to the reduction of 10 per cent. of the total quantity of milk. On the other hand, the proportion of full cheese should be, if possible, extended. Its value as an article of food is considerably higher than that of butter, and it has the advantage of greater permanence and easier transit. As the desirable consumption of full milk can hardly be increased it must be reserved as far as possible for the children. The matter may be summarised as

follows: "Full milk is to be retained in its present quantity, a production of cream and butter is to be limited, cheese is to be produced where possible in increased quantity. From the skim milk remaining after making butter, cheese (curds and skim) is to be made as far as possible, and the direct use of skim milk is also to be encouraged by propaganda and by cheap prices."

5. *Meat, fat*.—We must reckon with the fact that in the immediate future the number of pigs must be reduced by one-third and that of milch cows by one-tenth. In consequence of this the amount of meat on the market will immediately be increased, and if this is not to be followed by a subsequent meat famine immediate measures must be taken. The slaughtering must not be done all at the same time, and full advantage must be taken of the use of cold storage, smoking, pickling, and the production of *dauerwurst*. It would be especially advisable for the farmers themselves to prepare, as in old time, their own hams and bacons. If necessary the local authorities and the State must step in and buy up and preserve all the superfluous meat. The use of fat for technical purposes must be limited as far as possible. The employment for soap manufacture of fats, which could be used for human consumption, must be forbidden by the State. The soap manufactories can use the effluents of towns, as is already to some extent being done, and a house-to-house collection of waste fat is also possible. The addition to soap of substances which clean mechanically is also to be considered. Apart from soap, other industries must forego entirely the use of such fats.

Chapter X. considers

The Necessary Alteration in Habits of Life.

1. *More vegetable food*.—Even an isolated Germany can cover its requirements in foodstuffs, but to do so without too much limitation various adaptations must occur both in our agricultural production and in the proper utilisation thereof. Production and trade doing their part a moral duty rests with the consumer to do his, and to demand those foodstuffs, such as rye flour, sugar, and skim milk, which are at present in excess. The consumer, therefore, is entrusted with the great task of defeating the English starvation plan. The most pressing alteration demanded is to diminish the consumption of proteid and fat in comparison with that of carbohydrates, approaching more the habit of the country dweller, especially in South Germany. In wide circles, especially in towns, proteid has been consumed in excess in the form of meat, and we must reckon with the meat-supply becoming short after an initial glut. This reduction in itself is not an evil. The consumption of meat has increased enormously during the nineteenth century, as the following table, giving the relative consumption per head of population, shows:—

Year.	Kilos.	Year.	Kilos.	Year.	Kilos.	Year.	Kilos.
1816	13.6	1861	23.2	1883	29.3	1900	43.4
1840	21.6	1873	29.5	1892	32.5	1907	46.2

In the last ten years the consumption of meat has remained about the same, although it doubled during the previous 50 years. We can return to the habits of our forefathers in this matter without concern, and in so doing become healthier and live more cheaply. Fat also in the large towns has been used very abundantly in the form of bacon, lard, dripping, margarine, butter, and cream. Since in the rôle of nutrition it differs only from carbohydrates in a larger heating value—40 grammes of fat corresponding to 90 grs. of carbohydrate—we have only to replace this use of fat by more carbohydrates, such as bread, puddings, soups of various kinds, potatoes, sugar, &c., and this can and must be done. Fat will soon fail. The foreign animal fats—e.g., American lard and Siberian butter—are wanting, and also the fodder with which we have heretofore produced the home animal fats, especially oilcake, barley, and maize. We also lack the foreign vegetable fats which serve for artificial butter. An increased production of linseed oil and new sources, as, for instance, beech nuts and sunflower seeds, may help a little but not seriously affect the problem. Such a high consumption of fat is, however, as unhealthy as it is uneconomical. In contrast to most carbohydrates the pure fats are poor in other materials, especially in salts; and, by reason of their difficult digestion and lack of tempting flavour excite the consumption of alcohol, and are therefore hygienically questionable. Economically they are wasteful, as so much is lost on plates and dishes after becoming cold, as is shown by

Rubner's observation that 100 grammes a day are thrown away in Berlin per family. We must therefore use less fat and more carbohydrate, and since the animal foodstuffs contain more of the former and vegetable more of the latter the necessity arises of living more on vegetable substances. This is not a recommendation to pure vegetarianism. To give up animal food altogether would be economically a mistake, as the beasts consume stuffs unsuited for human food—e.g., hay, straw, greenstuff, acorns, beet parings, &c.—and these can only be made suitable for human food by being employed as fodder. We should only return to the habit of former times in which vegetarianism had no meaning, because the employment of meat and fat had not then reached such a high level. In a large part of South Germany the carbohydrates still form the principal part of the diet, and the necessary alteration for North and Central Germany consists in introducing South German dishes. The alteration should not be made too suddenly, and the State and local authorities should see to it that the prices of animal foodstuffs gradually rise, and so assist the gradual taking place of the change.

2. *Meat, fish; milk, cheese, skim milk; pulses.*—The body's need in building material—i.e., in proteid—will also be in part covered by the proteid content of bread, and in smaller degree of potatoes; and since these foods are taken for their carbohydrates in large quantities no inconsiderable amount of proteid is also taken. But to cover the whole proteid need excessive quantities of these would be required, and hence we do well to cover a part of our proteid requirement by foodstuffs containing a high proportion of proteid. There are three groups of these: (1) meat and fish; (2) milk and milk products; and (3) in the vegetable kingdom only the pulses.

The consumption of meat is very various in different parts of Germany. In some, especially in South Germany, little meat is taken—in the country for the most part only on Sundays, but in cities, and especially in the hotels and restaurants, the consumption is excessive. Excessive also is the so-called English breakfast, beginning the day with abundant quantities of meat, &c., and the employment of meat at the mid-morning lunch, to which even town children are accustomed. Wherever the employment has hitherto been within moderate limits it may be so continued. Meat remains to us permanently in various forms. In addition to beef, pork, and mutton, there is also available horse, game, poultry, rabbits, and, as fish may also be included under meat, both fresh water and salt fish, especially herrings, haddock, and cod. One of the cheapest sources of proteid is dried fish, and fortunately the herring catch of last year was a good one. Fish is especially useful in bringing variety into the diet of the poor. In hotels and restaurants part of the meat should be exchanged for fish, and for children meat is better replaced by milk and milk foods up to school years.

By far the most important substitutes for meat are milk, cheese, butter milk, and skim milk. Milk plays a special rôle among all foodstuffs, since, as the natural food of the young, it covers all that the body requires in each category of foodstuff. The consumption of butter should be limited, since it leads to a waste of skim milk used as fodder, and so to a large proteid loss. The consumption of full milk can hardly be increased, but should not be reduced; a certain redistribution should take place; employment for children instead of meat, skim milk taking the place of full milk for cooking. The consumption of cheese should be increased. Full cheese is, so to speak, concentrated milk, containing in convenient form practically all its valuable constituents, and it is more nourishing than moderately fat meat. It has the advantage over milk of appetising flavour, and for many people of greater digestibility. Milk costs in food value only about one-half of meat, and full cheese such as Tilsit, is cheaper even than milk on account of its convenient transport and keeping property. More important still is the production in future of skim cheese in larger quantities. As soon as the knowledge is general that with its proteid content and appetising flavour it is a cheap substitute for meat, bread and cheese will often take the place of bread and sausage. Unfortunately the use of curd cheese is limited. In contrast to full cheese, curd cheese has little flavour, but is on this account the more suitable for the preparation of breakfast and supper dishes even for children. It is especially suitable

for use in cakes and puddings, and already figures extensively in the South German and Austrian menu. Of great importance, too, is the use of skim milk to replace meat. As a beverage it has little vogue, but can often take the place of full milk in cooking and baking. In preparation of foods the taste is indistinguishable from that of full milk, and puddings are an excellent food for children and also for adults on days when meat is not taken. The greater employment of puddings, which by their content in skim milk, sugar, and flour replace fat, is not only a resource in time of urgent need, but a means of permanent importance for the nutrition of the people.

Lastly, as meat substitutes we have the vegetable products which are rich in proteid. Amongst these, far the most important are the pulses—peas, beans, and lentils. Their proteid content is equal to that of meat, but in consequence of the hard husk is much less digestible than that of meat or milk. But cooking can largely remedy this, especially in the case of peas, and they are therefore a cheap substitute for meat and should continue in use even with a rise of price. Nuts, chestnuts, and fungi, although rich in proteid, are of much less importance on account of their hard envelope.

3. *Bread, porridge, puddings, potatoes, vegetables.*—The body's need in energy-producers can just as well be covered by proteid and fat as by carbohydrate, but since we have to reckon in the future with a certain lack of the former, we must largely cover our need with the latter, and here starch-containing foodstuffs have the chief place—bread and other products of flour, potatoes, and vegetables. Taking bread first, the important matter is to add more rye and less wheat. Two million tons of foreign wheat have fallen out, and home-grown rye is available to take its place. This is an easy adaptation, since there is no good ground for preferring wheat bread to rye bread. The latter has hitherto been baked chiefly in large loaves, but is equally suitable for rolls. Fine rye flour without bran is also available. The Government has already ordained that flour must contain a certain proportion of bran (rye flour 72 per cent. of the whole, wheat flour 75 per cent. of the total weight of the grain), and this can be increased somewhat with advantage. If rolls of rye flour are demanded the baker will undoubtedly make them. Rye flour may also be used with advantage in the form of macaroni, groats, semolina, porridge, &c. These do not lead to the addition of fat to the same extent as bread does, and are therefore specially useful under present conditions, and the addition of skim milk and sugar greatly increases their nutritive value. Especially for children they have great application, and can in this way spare for adults the meat and fat rations to which they have been accustomed, although for the latter also reduced meat consumption is advisable. In South German and Austrian menus they already play a large rôle at breakfast and supper, with the addition or not of a little egg. Of potatoes we now consume some 14 million tons in the whole of Germany yearly, and employ about double the quantity for other purposes. In South Germany the consumption of potatoes can be greatly increased with advantage. The great loss on peeling, amounting to some 15 per cent., or yearly to 2 million tons, should be avoided. To avoid this potatoes should be boiled first and peeled afterwards. The taste of peel so resulting can be avoided by dropping the peeled potatoes into boiling salt water for three minutes. When peeled raw the patent peeler should be used, and dried potato chips have considerable application. Potatoes should be employed in greater variety, not merely boiled or as salad but in the form of dishes with the addition of a little meat or fish, or with cabbage, fruit, &c. A special place is occupied by vegetables. The chief value of bread, puddings, &c., lies in their starch content. Vegetables also contain a certain quantity of starch, some also a little proteid, but their value in nutrition is chiefly due to other constituents. The mineral stuffs, especially chalk and iron, are of some value, but their chief use is as appetisers on account of their varied and agreeable taste, thus making more change possible in the diet, especially when this contains a large quantity of potatoes, and in so doing they further limit employment of fat.

4. *Fruits, sugar.*—The second kind of carbohydrates which must help us to cover the supply of energy-producers we find in the sugar-containing foods, especially in fruits and in the sugar which is obtained from beets. Fruits play a similar rôle to that of vegetables, although the sugar

content is 15 per cent. in grapes, 8 per cent in apples, but only 2 per cent. in whortleberries. Fresh fruits have the objection of not keeping, and preserving makes it possible to utilise the less valuable kinds and to store and transport them. The use of sugar must be largely increased, bearing in mind that in England and America it is twice as much per head of population as with us. In those countries preserves are largely used where we use butter. Exact investigations have shown that taking of some 12 to 15 grammes of sugar in half-hourly intervals can remove the sense of fatigue in very large measure. Hence, sugar in various forms should be part of the consignments to the troops in the field. The frequent assumption that the use of dry sugar produces thirst is incorrect; on the contrary, it produces increased salivation, and thereby moistens the mouth. The production of thirst is unthinkable, because in the oxidation of sugar in the body almost two-thirds of its weight of water is formed. No large amount of raw sugar can be taken, but it can be made up into cheap fruit preserves and various forms of cakes and sweet dishes and as an addition to soured milk. Sugar added to tea and coffee is no luxury, but makes these drinks nutritious. It must be borne in mind that sugar is not merely a sweetmeat but weight for weight equivalent as a foodstuff to fine flour.

5. *Household economy.*—"Much should be otherwise in our nutrition. Vegetable food must take a larger place. At the midday meal the meat dishes should be placed in the background and various valuable puddings take their place. But it is a question not only of an alteration of the chief meals, but also of much else. Rolls should be confined to breakfast; at dinner and supper large loaves of rye flour or rye and wheat flour. The widespread but senseless luxury of eating bread between meals with a layer of fat should be given up. Bread alone is sufficient, or bread with fruit or marmalade. With fat dishes such as cheese or ham, buttered bread is entirely unnecessary." With the alterations recommended, our diet will not be monotonous but more varied. In many circles the present menu is poor in variety and it is only to be wished that particular dishes at present not enough valued should be introduced. The housewife must take care that the alteration of the diet should not produce disgust. Newly introduced sweet dishes should alternate with the more usual salt or acid ones, and excessive zeal may do great harm and only produce the effect of a hurried return to the old unsatisfactory diet. An important item is the home production of articles of diet. Even a small piece of garden can cover part of the requirements in potatoes and vegetables, and the keeping of animals must be considered. Pigs, goats, rabbits, and hens make it possible to use all the kitchen refuse, such as potatoes and withered vegetables. In most cases it will be possible to pickle and smoke meat and to preserve vegetables and fruit. Correct marketing must be practised everywhere. Where necessary articles such as skim milk, fruit, cheese, and rye rolls are not offered in sufficient quantity, they should be repeatedly demanded, so that demand may call forth supply. In general it is not advisable to store food, apart from some pickles and smoked meat, as well as preserved fruits and vegetables.

Finally, care must be taken that no waste occurs, as has been too much the case in all classes of society. Among the well-to-do too much has been eaten. Superfluous nourishment is partially undigested and floods the body to the detriment of health. But apart from this much goes bad both in the kitchen and on the table, and the value of refuse has been little recognised. All meat and fish scraps should be carefully utilised. They can be boiled and employed to flavour soups and vegetables. The remains of fats and sauces especially should be kept, as well as those of bread and potatoes. Waste of food may also occur in the use of spirit, starch, and soap, for the two former are made from grain and potatoes, while the latter is chiefly produced from useful fat. The spirit producers have recently pointed out that with the shortage of petroleum, spirit is a useful substitute. This is correct, but we should make as little use as possible of the substitute, since as spirit is produced from potatoes the burning of spirit is equal to the burning of potatoes. Wherever other illumination is available spirit should not be used. The same applies to starch, which is produced from potatoes, for although in the case of linen its use can hardly be avoided, for other articles of dress it should be given up entirely, as it is not only uncomfortable, but prevents the passage of air and is actually unhealthy.

In a time in which it is necessary to economise our food-supply it is stupid to persist in so doubtful a fashion. Finally, in the washing of clothes soap should be sparingly used, especially as hard water wastes it in large measure. For one degree of hardness—i.e., 10 milligrammes of chalk in the litre of water—denotes for a hectolitre of water a loss of 10 grammes of the usual commercial soap. In a hard water, such as that of the Jura, the loss may amount to 350 grammes or more of soap for a hectolitre. In these regions it is advisable to use rain water, or, if this is impossible, to soften the water previously with soda, chlorine compounds, or perborates. Some saving of nutritive value is possible by the preparation of food in quantity, but, in general, cooking at home is both better and more economical. The self-cooker may render additional assistance. Where the housewife has to work outside the house a people's kitchen may then serve a useful purpose.

The Covering of the Deficit.

Chapter XI. treats of results, and contains the following interesting summary:—

Nutritive values.	Proteid in thousands of tons.	Calories in milliards.
Physiological requirement	1605.0	56750.0
Actual use before the war	2307.0	90420.0
Available if the present conditions remain unaltered... ..	1543.0	67860.0
To add: Alteration of cattle-keeping	217.3	2878.0
Avoidance of waste	80.0	5675.0
Prohibition of corn as fodder	78.3	2741.0
Increased use of skim milk and skim cheese	48.8	250.9
Potato-drying	18.9	1112.3
Limitation of butter production	14.8	110.4
Cultivation of moors	10.4	592.0
Prohibition of the production of alcohol from corn	4.7	68.6
Preserving of vegetables	3.6	93.0
Preserving of fruit	1.7	147.5
Prohibition of the production of wheat-starch	1.3	5.2
To subtract: Sugar used as fodder... ..	—	— 283.1
Available if the means recommended are carried out	2022.8	81250.8

"We see that the efficacy of the means recommended is great. The available amount of foodstuffs rises very considerably, the number of calories by 20 per cent., the proteid by 30 per cent. Our needs are covered also in regard to proteid, and in so large a degree that the losses involved in transit are covered. The available calories exceed our needs by 44 per cent., the available proteid by 26 per cent. Naturally it is inconceivable that without imports the same amount of nutritive value should be available as before the war, but an approach to this amount is obtained in calories, wanting instead of 25 per cent. only 11 per cent., in proteid instead of 33 per cent. only 13 per cent. of what was available before.

"This favourable result applies not only for the moment but permanently, even if the war should last for years. It has intentionally been left out of consideration what might cover our immediate needs, but is not assured for longer—both our reserve stores and our imports from neutral States. Indeed, the possibility has been reckoned with that during the war our production in food values may be still further diminished by bad harvests and other causes.

"The favourable result has not been assumed with thoughtless optimism, but has been worked out with gravity and foresight. In reckoning our requirement and our sources of help they have been assumed in general to be too low rather than too high. The requirement of the individual has been fixed as if the whole population were well whereas we have numerous sick people with reduced needs. For the needs of the whole people a census of 68 millions has been assumed, although the greater part of the army is on hostile land. Of the means for producing food-values there are many which cannot be expressed in figures—as, for instance, the internal colonisation, the increased cultivation

of pulses, the extended keeping of small animals—and for the remainder the smallest amount has always been worked out and stated.

"The whole favourable result naturally assumes that what is here demanded will actually happen, that the Government permit no export of foodstuffs, that the local authorities carry out strictly the prohibition of corn as fodder, and that the farmer sees that the head of swine are reduced by 9 millions, the head of milch-cows by 1 million, that the waste of fodder as well as of foodstuffs shall cease in our households, that a sufficient number of prisoners of war can be had for the culture of moors, and so on. But this assumption will be fulfilled.

"We shall come through. That we can do so we owe to our agriculture, under the mighty protection of our rulers, who with clear sight recognised the danger of a one-sided development of Germany into an industrial state, and with the able coöperation of prominent men it has in the last decades undergone a tremendous increase; to its own benefit, and with the gratifying result that we are in a position, in case of need, to nourish on an area of little more than half a million square kilometres 68 millions of human beings without import from abroad. To the healthy adaptability of our economical life we are also greatly indebted. As the individual adapts himself the more easily to a change in outside circumstances the better his nervous system reacts; so also the national economy shows a greater adaptive power, the more nervous force works in it in the form of strong, intelligent, thoroughly sound personalities. The richness of Germany in such personalities has shown itself since the outbreak of the war in surprising manner. But before all must we be thankful for two qualities of our national character, which perhaps we have not always sufficiently prized—viz., clearness and persistence. On these the authors of this work build, when they cherish the conviction that, spite of closed frontiers and suppression of sea trade, the English starvation plan will founder on the free working together of our millions."

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Temporary Surgeons: A. McMillan to the *Egmont*; A. E. Iles to the *Victory*, additional, for Haslar Hospital; H. P. Margetts to the *Victory*, additional, for disposal; and W. E. Fox to the *Laurentic*.

ROYAL NAVAL RESERVE.

The undermentioned have been granted temporary Commissions as Surgeons in His Majesty's Fleet: Frederick Harold Rees and Stanley Worthington.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon Charles Samuel Brewer to be Honorary Staff Surgeon (dated Feb. 11th).

Staff Surgeon: A. R. Brailey has been appointed to the *Victory*, additional, for Haslar Hospital.

ARMY MEDICAL SERVICE.

Colonel James M. Irwin is retained on the Active List under Article 120, Royal Warrant for Pay and Promotion, and to be supernumerary (dated Feb. 13th).

Major Henry M. W. Gray, Royal Army Medical Corps, Territorial Force, to be temporary Colonel (dated Feb. 1st).

ROYAL ARMY MEDICAL CORPS.

Major John M. Buist is placed temporarily on the Half-pay List on account of ill-health (dated Feb. 6th).

Temporary Captain George E. Miles to be temporary Major (dated Feb. 17th).

Temporary Lieutenant William Anderson, having ceased to serve with the British Red Cross Hospital, Netley, relinquishes his commission (dated Feb. 2nd).

The undermentioned to be temporary Captains:—Dated Jan. 21st: John Curtis Webb. Dated Jan. 23rd: John Joseph Esmonde.

Lieutenant Cecil Corbin relinquishes his temporary commission (dated Feb. 7th).

Lieutenant Charles E. Reckitt relinquishes his temporary commission (dated Feb. 1st).

Mervyn Henry Gordon is granted temporarily the honorary rank of Major (dated Feb. 2nd).

Supernumerary Captain Travis C. Lucas is restored to the establishment (dated Jan. 5th).

Lieutenant Arthur A. Martin relinquishes his temporary commission (dated Feb. 2nd).

Temporary Lieutenant Kenneth William Mackenzie, late Captain, Indian Medical Service, to be temporary Captain (dated Feb. 16th).

Temporary Lieutenant Norman W. Anderson relinquishes his commission (dated Feb. 16th).

The undermentioned to be temporary Lieutenants:—Dated Jan. 21st: Ulick Joseph Bourke and Horace Nathaniel Everard. Dated Jan. 22nd: Bertram Henry Barton and George Flett Barr. Dated Jan. 24th: Peter Hay MacDonald. Dated Jan. 25th: Thomas Henry Brown, John Ellison, Charles Leslie Wigan, John Charles Robb, William Samuel Heron, George McCallum, Roger MacGrath, Cedric Norman Vaisey, and Leslie Alexander Drake. Dated Jan. 26th: Thomas Reginald Trounce, Martin Phillips Thomas, George Michael De Vines, Henry Joseph Cotter, and Thomas Small Goodwin. Dated Jan. 27th: John Stuart Prentice and William John Alexander Bruce Wishart.

SPECIAL RESERVE OF OFFICERS.

Supplementary to Regular Units or Corps: Royal Army Medical Corps.

Lieutenant James F. Quigley resigns his commission.

TERRITORIAL FORCE.

Royal Army Medical Corps.

The undermentioned to be Lieutenants (on probation); Stanley Burrough King and Second Lieutenant Owen Parry-Jones from General Reserve of Officers.

1st East Anglian Field Ambulance: Hugh Frederick Gethin Hall to be Lieutenant.

3rd London General Hospital: Alfred Hope Gosse to be Lieutenant.

4th Scottish General Hospital: William Archibald Campbell to be Captain, whose services will be available on mobilisation.

3rd Southern General Hospital: Frank Gower Gardner to be Lieutenant.

Sanitary Service: Major Alfred Greenwood to be Lieutenant-Colonel (temporary); Major Francis E. Fremantle to be Lieutenant-Colonel (temporary); and George Henry Weston (late Lieutenant, 2nd Volunteer Battalion, Hampshire Regiment), to be Captain, whose services will be available on mobilisation.

1st South Midland Field Ambulance: Major William M. Sturrock to be Lieutenant-Colonel (temporary).

3rd North Midland Field Ambulance: James Ernest Sutcliffe Smith to be Lieutenant.

1st Northern General Hospital: Captain William T. Harkness, from the Northumbrian Casualty Clearing Station, to be Captain.

Eastern Mounted Brigade Field Ambulance: Kenneth Bleckly Clarke to be Lieutenant.

1st East Anglian Field Ambulance: Ambrose Cyril Wilson to be Lieutenant.

2nd Home Counties Field Ambulance: George Mortimer McGilivray to be Lieutenant.

1st East Lancashire Field Ambulance: Gilbert Bailey to be Lieutenant.

1st West Lancashire Field Ambulance: Captain John E. W. McFall to be Major (temporary).

1st Northumbrian Field Ambulance: Home Alexander Playfair Robertson to be Lieutenant.

1st Welsh Field Ambulance: Major John Howard-Jones to be Lieutenant-Colonel (temporary). Captain John O'Sullivan to be Major (temporary).

2nd Welsh Field Ambulance: To be Lieutenants: David Thomas Lewis and Thomas Peters Edwards.

1st Southern General Hospital: Ernest Cordley Bradford to be Lieutenant.

West Lancashire Casualty Clearing Station: Harry Driffeld Levick to be Lieutenant.

Attached to Units other than Medical Units.—Lieutenant-Colonel and Honorary Surgeon-Colonel George Hollies resigns his commission on account of ill-health. To be Majors: Major Peverell S. Hichens, from 1st Eastern General Hospital, and Captain James Aitken (temporary). To be Captains: Robert William Meikle (late Captain, Royal Army Medical Corps, Territorial Force) and Charles Stewart Young (late Surgeon-Captain, 3rd Volunteer Battalion, Royal Highlanders). Lieutenant Herbert W. Joyce resigns his commission on account of ill-health. To be Lieutenants: Gerald Francis Carr, Frederick William Arthur Stott, Arthur Henry Fullerton (late Lieutenant, 1st Volunteer Battalion, East Yorkshire Regiment), and Walter Smart.

ADMINISTRATIVE MEDICAL APPOINTMENTS IN INDIA.—Colonel C. E. Nicol, D.S.O., British Service, has been appointed to officiate as Assistant Director of Medical Services, 5th (Mhow) Division; and Lieutenant-Colonel G. G. Adams, R.A.M.C., has been appointed to officiate as Assistant Director of Medical Services, Jubbulpore and Jhansi Brigades.

Lieutenant-Colonel T. A. Granger, I.M.S., has been appointed Honorary Surgeon to H.E. the Viceroy of India.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last census, 8971 births and 6558 deaths were registered during the week ended Saturday, Feb. 13th. The annual rate of mortality in these towns, which had been 18.0, 19.2, and 20.1 per 1000 in the three preceding weeks, fell in the week under notice to 18.9 per 1000 of their aggregate population, estimated at 18,134,239 persons at the middle of 1914. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 19.1, against 19.9 per 1000 in London. The annual death-rate last week ranged from 8.7 in Wimbledon, 10.9 in Bournemouth and in Smethwick, 11.3 in Bolton, 12.0 in Enfield and in Ilford, and 12.3 in Bury, to 29.1 in Gillingham, 29.2 in Northampton, 29.6 in Carlisle, and 32.5 in Cambridge and in Merthyr Tydfil.

The 6558 deaths from all causes were 437 fewer than the number in the previous week, and included 511 which were referred to the principal epidemic diseases, against numbers rising from 454 to 513 in the four preceding weeks. Of these 511 deaths, 207 resulted from measles, 125 from whooping-cough, 70 from infantile diarrhoeal diseases, 66 from diphtheria, 27 from scarlet fever, and 16 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1.5, against 1.4 and 1.5 per 1000 in the two preceding weeks. The deaths attributed to measles, which had been 206, 191, and 210 in the three preceding weeks, slightly fell to 207 last week, and caused the highest annual death-rates of 1.7 in Tottenham and in Enfield, 1.8 in Stockton-on-Tees, 1.9 in Barnsley, 2.0 in Grimsby, 2.4 in Rotherham, 3.1 in St. Helens, 4.9 in Merthyr Tydfil, 5.2 in Gateshead, and 5.3 in Darlington. The deaths referred to whooping-cough, which had increased from 76 to 123 in the four preceding weeks, further rose to 125 last week; the highest rates from this cause were 1.6 in Bristol, 1.7 in Reading, 1.9 in Willesden and in Dewsbury, 2.0 in Carlisle, and 3.1 in Merthyr Tydfil. The fatal cases of diarrhoea and enteritis (among infants under 2 years of age), which had been 62, 73, and 68 in the three preceding weeks, rose to 70 last week, and included 17 deaths in London, 9 in Liverpool, and 4 each in Stoke-on-Trent and Birmingham. The deaths attributed to diphtheria, which had been 83, 77, and 72 in the three preceding weeks, further declined to 66 last week, of which 16 occurred in London, 6 in Manchester, 5 in Birmingham, and 4 in Sheffield. The deaths referred to scarlet fever, which had been 23, 31, and 22 in the three preceding weeks, rose to 27 last week, and included 13 in London and 2 in Leeds. The fatal cases of enteric fever, which had been 12, 12, and 17 in the three preceding weeks, were 16 last week, of which 4 belonged to London and 2 each to Brighton, Blackburn, and Gateshead.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 5035 to 3395 in the 11 preceding weeks, had further fallen to 3299 on Saturday last; 368 new cases were admitted during the week, against 308, 326, and 365 in the three preceding weeks. These hospitals also contained 1676 cases of diphtheria, 219 of measles, 58 of enteric fever, 16 of whooping-cough, and 3 of small-pox. The 1696 deaths from all causes in London were 163 below the number in the previous week, and corresponded to an annual death-rate of 19.6 per 1000. The deaths referred to diseases of the respiratory system, which had been 417, 450, and 497 in the three preceding weeks, declined to 455 in the week under notice, but were 193 in excess of the number recorded in the corresponding week of last year.

Of the 6558 deaths from all causes in the 96 towns 175 resulted from different forms of violence and 456 were the subject of coroners' inquests, while 1805 occurred in public institutions. The causes of 45, or 0.7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Sheffield, Leeds, Bristol, West Ham, Bradford, Hull, and in 70 other smaller towns. Of the 45 uncertified causes of death 9 were registered in Liverpool, 8 in Birmingham, 4 in Gateshead, 3 each in London and Preston, and 2 each in Stoke-on-Trent, Blackpool, and Carlisle.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1132 births and 1037 deaths were registered during the week ended Saturday, Feb. 13th. The annual rate of mortality in these towns, which had been 21.7, 22.4, and 24.1 per 1000

in the three preceding weeks, declined to 23.1 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 23.1, against 19.1 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 13.5 in Hamilton, 15.1 in Motherwell, and 16.0 in Paisley, to 28.9 in Falkirk, 36.8 in Perth, and 37.4 in Dundee.

The 1037 deaths from all causes were 49 fewer than the number recorded in the previous week, and included 122 which were referred to the principal epidemic diseases, against numbers rising from 92 to 147 in the four preceding weeks. Of these 122 deaths, 81 resulted from whooping-cough, 14 from infantile diarrhoeal diseases, 11 from measles, 8 from scarlet fever, 6 from diphtheria, and 2 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2.7, against 1.5 per 1000 in the large English towns. The deaths attributed to whooping-cough, which had steadily increased from 28 to 86 in the seven preceding weeks, fell to 81 last week, of which 42 occurred in Glasgow, 20 in Dundee, 5 in Greenock, and 4 in Edinburgh. The deaths of infants (under 2 years) referred to diarrhoea and enteritis, which had increased from 7 to 16 in the four preceding weeks, fell to 14 last week, and included 5 deaths in Glasgow, and 2 each in Dundee, Leith, and Clydebank. The fatal cases of measles, which had been 7, 6, and 13 in the three preceding weeks, fell to 11 last week, of which 9 were registered in Dundee. The deaths attributed to scarlet fever, which had been 16, 12, and 17 in the three preceding weeks, declined to 8 last week, and included 4 in Glasgow and 2 in Falkirk. The deaths referred to diphtheria, which had been 8, 10, and 13 in the three preceding weeks, fell to 6 last week, of which 2 were recorded in Glasgow. The 2 fatal cases of enteric fever belonged to Glasgow and Coatbridge respectively.

The deaths referred to diseases of the respiratory system, which had been 238, 272, and 302 in the three preceding weeks, fell to 278 in the week under notice, but were 131 in excess of the number recorded in the corresponding week of last year; 35 deaths resulted from different forms of violence, against 30 and 35 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,212,330 persons at the middle of this year, 680 births and 615 deaths were registered during the week ended Saturday, Feb. 13th. The annual rate of mortality in these towns, which had been 24.0, 24.7, and 26.2 per 1000 in the three preceding weeks, further rose to 26.5 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 25.5, against corresponding rates of 19.1 and 23.1 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 28.0 in Dublin (against 19.9 in London and 21.6 in Glasgow), 24.6 in Belfast, 39.4 in Cork, 27.8 in Londonderry, 23.0 in Limerick, and 13.3 in Waterford, while in the 21 smaller towns the mean death-rate was 24.3 per 1000.

The 615 deaths from all causes were 6 in excess of the number recorded in the previous week, and included 44 which were referred to the principal epidemic diseases, against 32 and 38 in the two preceding weeks. Of these 44 deaths, 17 resulted from whooping-cough, 13 from infantile diarrhoeal diseases, 5 from measles, 4 each from scarlet fever and diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1.9, against 1.5 and 2.7 per 1000 in the English and Scotch towns respectively. The deaths attributed to whooping-cough, which had been 9, 11, and 13 in the three preceding weeks, further rose to 17 last week, of which 10 were recorded in Dublin and 3 in Cork. The deaths of infants (under 2 years) referred to diarrhoea and enteritis, which had been 4, 8, and 10 in the three preceding weeks, further rose to 13 last week, and included 8 in Dublin and 2 in Belfast. The 5 fatal cases of measles, of which 3 occurred in Belfast, were 3 in excess of the average in the earlier weeks of the year. Of the 4 deaths attributed to scarlet fever 3 occurred in Belfast. Two of the 4 deaths from diphtheria and the fatal case of enteric fever were registered in Dublin. In addition to the above deaths, a fatal case of typhus occurred in Galway.

The deaths referred to diseases of the respiratory system, which had been 137, 160, and 172 in the three preceding weeks, further rose to 182 in the week under notice. Of the 615 deaths from all causes, 175, or 28 per cent., occurred in public institutions, and 6 resulted from different forms of violence. The causes of 25, or 4.1 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the English towns the proportion of uncertified causes did not exceed 0.7 per cent.

Correspondence.

"Audi alteram partem."

MILD SMALL-POX.

To the Editor of THE LANCET.

SIR,—In connexion with an annotation in THE LANCET of Feb. 13th, may I add a word on the subject, as I was unavoidably absent from the meeting of the Section of Epidemiology of the Royal Society of Medicine at which Dr. J. B. Cleland and Dr. E. W. Ferguson reported on the outbreaks of small-pox in Australia?

Studying the disease during successive years, I came to the conclusion that it was not safe to make any statement about it without consulting Sydenham, and students of these present mild outbreaks would have done well, as Dr. McPhail reminded them in the discussion, to look up the history of prevaccination outbreaks. The extraordinary difference in their virulence was not only recognised by Sydenham, but by Van Swieten, Mason Good, Jenner, and others. Mason Good mentions that in his own case (1770) he had not more than 20 scattered pustules, and Jenner describes an epidemic as mild and light as the inoculated variety. All the same, it is not a pleasant experience, as happened in my wards, to have an outbreak arise and not reach a diagnosis until the seventh or eighth case proves to be one of confluent small-pox! One unvaccinated child had not more than half a dozen superficial pustules, and Welch and Schamberg report an instance with a single pox. Apart from the low virulence, an interesting feature of many of the recent American outbreaks has been the high percentage of unvaccinated attacked—96 out of 97 cases in the outbreak at Carbondale, Pennsylvania (1912).

With this history one cannot agree with the conclusion of Dr. Cleland and Dr. Ferguson that in Australia or elsewhere small-pox is unlikely to recover again its general intense virulence.

I am, Sir, yours faithfully,

Oxford, Feb. 13th, 1915.

WILLIAM OSLER.

FROST-BITE.

To the Editor of THE LANCET.

SIR,—The paper by Mr. A. W. Mayo-Robson on Frost-bite, which appears in THE LANCET of Jan. 16th, is timely. The subject is certainly one of the most interesting, and is among the most novel of those which have come under our consideration since the beginning of this war. The severity of the cases which we have had in Rouen has varied within the widest limits. There are cases in which no appreciable changes have taken place in the appearance of the limbs, yet the whole of the skin, especially that on the inner side of the foot and on the dorsum of the toes, is acutely hypersensitive even to the lightest touch. There are, at the other extreme, cases in which to all appearance the whole foot is doomed to gangrene.

I am not, however, at this moment so much concerned with the various grades of injury, with the means by which the condition is produced, nor with the absolute necessity in all cases of conservative treatment. I wish more particularly to give a hint with regard to the care of these patients. A great variety of methods of local treatment have been

tried: turpentine and lanoline applications; thorough cleansing and drying, followed by the swathing of the foot in boracic acid powder and wool; painting with tincture of iodine; and so forth. I really think that, apart from the pain inflicted, there is no appreciable difference in the results of these or other methods. At one time all cases were treated by local applications, over which was a covering of wool with a bandage. It is usual to hear the statement made that great pain is suffered by many, indeed by almost all, of the patients. The pain at times may be so severe as to call for morphine or opium for its relief. The pain, however, is due, not so much to the damage inflicted upon the parts, but to the fact that the feet are kept warm.

During the last few weeks here the majority of the patients have had little or no dressing applied. The parts affected are smeared with some ointment, covered with a thin layer of gauze, and left without wool or bandage. The feet are often raised a few inches from the bed upon a hard pillow. The lower part of the legs and the feet are covered in bed only by a sheet. It has been our experience with few exceptions to find that the pain is very considerably lessened or abolished by keeping the parts cold. A patient whose feet have been well wrapped up and bandaged and who has suffered nights of torture will experience relief in a few hours when the bandages are removed and the bedclothes are turned back.

Pain, it may truthfully be said, is almost exactly proportioned to the degree of warmth of the foot. Seeing that, whatever the local treatment, the progress towards recovery in the foot appears to be equally rapid, it is the relief of pain during the time of healing that should be our chief consideration.

I am, Sir, yours faithfully,

Feb. 13th, 1915.

BERKELEY MOYNIHAN,

THE POSITION OF THE FRENCH RED CROSS IN ENGLAND.

To the Editor of THE LANCET.

SIR,—The attention of our committee has been called to an appeal in your issue of Feb. 6th, p. 303, on behalf of the Wounded Allies Relief Committee for £100,000 for the purpose of establishing or maintaining certain Anglo-French hospitals in France. The admirable work done by THE LANCET since the war began in aid of the wounded of all nationalities makes one hesitate to offer anything that may even savour of criticism. At the same time, in the best interests of at any rate the French wounded, it seems well to call attention to certain facts.

There is no doubt that in some of the distant fields of strife—Serbia, for instance—there is ample scope for new societies and fresh individual effort. In the case of the French, however, these considerations do not apply, and the advocacy of new societies established through the enthusiasm of doubtless sincerely well-meaning people can result only in loss of coördination, overlapping, and not infrequently inevitable friction with thoroughly established and fully recognised organisations. France has had for many years three excellent organisations for rendering assistance to the injured in any public calamity. These are: La Société Française de Secours aux Blessés, l'Union des Femmes de France, and l'Association des Dames Françaises. As regards the organisation of help from this country, the French Government,

acting through the Ambassador, has officially appointed the London Committee of the French Red Cross, under the presidency of the Vicomtesse de la Panouse, to represent these three societies, which have in their charge practically the whole of the voluntary care of the wounded French. It provides surgeons, nurses, orderlies, and stores of all kinds for the French voluntary hospitals. It assists in a great many similar ways the British hospital units which have been established by private generosity in France. Most of these, unless actually under the control of the British Red Cross Society, have found it to their advantage to become affiliated to the above London Committee of these three great French societies and to work through it.

This committee has also elaborated a system whereby British surgeons who are good enough to volunteer their services for a month or more can be found suitable posts. Further, the London Committee of the French Red Cross being in intimate official relations with the French Government will be able to make the best arrangements for hospitals and new centres when the movement of the armies we all hope for takes place. It is therefore evident that as far as the French wounded are concerned there is absolutely no need for further societies, and it is certainly inadvisable to distribute subscriptions amongst new organisations for hospitals which may or may not continue, or be allowed to continue, to exist. Such a course, in addition to the inconveniences already mentioned, can only lead to waste of time, energy, and money.

I therefore venture to appeal to intending subscribers wishful to help in the most certain and efficient manner the wounded of the French armies, who have so gallantly held more than 250 miles of the Western battle line, to concentrate their efforts and contributions in favour of the London Committee of the French Red Cross (of which the honorary secretary is Mr. P. A. Wilkins, 25, Knightsbridge, London, S.W.), which is in a position to send the help to the points where it is most needed.

I am, Sir, yours faithfully,

JAMES DONELAN,

Medical Referee to the Committee.

Manchester-square, W., Feb. 15th, 1915.

THE ETIOLOGY OF POLIOMYELITIS.

To the Editor of THE LANCET.

SIR,—Dr. J. T. C. Nash in THE LANCET of Jan. 16th asks for further information regarding the cases of poliomyelitis at West Kirby. In the first place, he wishes to know the distance of each infected house from the nearest stable. I am sorry I am not in a position now to give the exact distance, but in no case, I believe, was a stable situated near, or what one usually considers near. With regard to the second point, I understand the same horse and cart took round the milk, so that there is nothing here incompatible with Dr. Nash's theory that stomoxys calcitrans may be carried considerable distances, following or resting on a horse. When investigating the cases, however, I was more impressed by the possibilities and probabilities of human carriers being concerned, and even that one of the distributors of milk was the likely source of infection.

The first case in the last outbreak at West Kirby was the son of a medical man who had attended cases of the previous year. It is interesting to recall that when the late Dr. R. Burnet, of Cornwall, was investigating the outbreak of polio-

myelitis in that county four years ago his only son fell a victim to the disease, probably being infected by his father. There is, I think, a growing body of evidence in favour of the theory of poliomyelitis being spread by the agency of human carriers.

I am, Sir, yours faithfully,

Hartlepool, Feb. 15th, 1915. GEORGE JUBB, M.D., D.P.H.

FAITH AND ASTIGMATISM.

To the Editor of THE LANCET.

SIR,—If it should ever be my misfortune to be tried for my life at the Old Bailey or elsewhere I shall not attempt to obtain the services of Mr. Reginald Evershed as my advocate, for if I did there can be little doubt my state of suspense would very soon end in one of suspension.

Mr. Evershed, in THE LANCET of Feb. 6th, is particularly unfortunate in the case he quotes to support the views of the refraction extremists. Which idea does he hold: that the discovery of the extra 1/4 diopter of astigmatism in the one eye cured the patient? or the mysticism of Prey's letters, &c., and the probable reassurance given him that the glasses would do so? Is not Mr. Evershed between two horns of a dilemma? A dignified silence is a useful thing to maintain when you cannot maintain anything else, and the attitude shown by the two original contributors to the subject may well be commended to Mr. Evershed, at least until he is on surer ground.

Now, Sir, I did not write my first letter with a view to depreciating the shares of the Langham Hotel or of the railways converging upon Harrogate. Far from it. My intention was to disclaim—for myself at any rate—the extreme views held by some members of my specialty in this country which tend to bring the holders and the specialty into ridicule at the hands of the more moderate members of the profession who, fortunately, are in a great majority. Extremists are deficient in the sense of proportion, and specialists are apt to suffer from the same disorder, especially if they specialise too early. My own opinion is that no one should take up any specialty until he or she has had ten years' experience of general practice. Such a practitioner gets out of the way of looking at things and people through the same pair of spectacles. Refraction extremists are by no means confined to this country, and across the herring pond is one of their archpriests, who is so extreme that I quite look forward to his asserting some day that St. Paul's thorn in the flesh was really a refraction error, and that if only the German Emperor had paid a visit to his "office" this horrible war would certainly have been prevented. And though prevention is better than cure, yet since it is claimed by some that a tendency to insanity can be cured by suitable correcting lenses, would it not be well to appoint one of these gentlemen ophthalmic surgeon to Bedlam? Who knows how many of the unfortunate inmates thereof might be cured or relieved by a pair of spectacles? *Quis dubitat?*

We see extremes and extremists everywhere—e.g., in politics the advanced Radical thinks nothing good can come from the opposite party and *vice versa*; in the Church, the extreme High Church cleric, who plays croquet on Sunday afternoon, would shrink from burying a Dissenter in his churchyard, whilst another would be only too pleased to bury the whole of them there; or the eugenist crank who insists upon our marrying Mary when we feel we can only be happy with

Jane in spite of the small strawberry mark on her arm; and so on, and so on. Extremists, of course, have their place in the sun and do some good. They tend to develop the antibodies of moderation and make us challenge and prove all things, holding fast to that which is true, which, in the long run, is invariably found to be moderate. But, Sir, even in the length of one's epistles to the Editor of THE LANCET one must study the science and practise the art of moderation, and to escape the opposite soft impeachment I will at once subscribe myself

Yours faithfully,

Norwich, Feb. 13th, 1915.

S. JOHNSON TAYLOR.

THE SUPPLY OF LOCUM TENENTS.

To the Editor of THE LANCET.

SIR,—May I trespass on your space for a few remarks on this very vital question? When war broke out necessarily a large number of medical men who belonged to the Royal Army Medical Corps were immediately obliged to take up their duties, and many others have in ever-increasing numbers since loyally and patriotically in obedience to their country's call voluntarily thrown up lucrative practices and applied for commissions, and by no means a small number have enlisted in the fighting ranks.

Necessarily, therefore, a largely increased demand has arisen for locum tenents to safeguard the practices at home of those who have nobly offered their services and lives for England's honour. Owing to many of those who had hitherto been available as locum tenents also responding to the call it has become increasingly difficult to find enough reliable substitutes, and I regret to have to say that there is a tendency on the part of a few to take advantage of the shortage to demand fees quite incompatible with the services rendered. May I through your columns implore all who are in any way able to take up duty again to offer their services in the present crisis?

I am glad to say that many retired practitioners up to 70 years of age have loyally come forward and most satisfactorily filled some of the gaps, and some of our Belgian Allies who can speak English a little have been of great assistance for temporary work, but more are urgently needed if we are to ensure that the practices of those who have so nobly rallied round the flag shall not suffer. There is plenty of work for every available qualified man, especially if prepared to show his patriotism and loyalty to his profession by accepting fees in some measure proportionate to the size of the practice he is taking charge of.

I am, Sir, yours faithfully,

Adam-street, Adelphi, Feb. 8th, 1915. PERCIVAL TURNER.

SULPHUR AND RHEUMATISM.

To the Editor of THE LANCET.

SIR,—In reference to what Sir Lauder Brunton says about sulphur and rheumatism in your issue of Feb. 6th, I think the following case is to the point. A patient, aged 55 years, had suffered from joint pains, called rheumatism, since he was 19 fairly continuously, and no treatment did him any good. It happened that he took sulphur for the relief of an attack of lumbago and continued it for some four months as a prophylactic. His rheumatism was completely cured and has remained so for some six years, during which he

has continued to take two or three troch. sulph. two days a week. The essence of the treatment as a cure is that it should go on some months before the cure is likely to obtain.

I am, Sir, yours faithfully,

Harley-street, W., Feb. 13th, 1915.

SHEFFIELD NEAVE.

THE SHORTAGE OF RESIDENT MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—Dr. R. R. Rentoul's letter in your last issue, which somewhat severely comments on mine of Feb. 6th, has been the means of my discovering that in my letter the word "voluntary" is inserted before the word "residence," thereby giving the impression that we wished to get the doctors' services for nothing. Such is far from the case; we are quite ready to pay such doctors even more than the "lost dog's wage," which Dr. Rentoul mentioned as the ordinary rate of pay. If we cannot pay the princely salaries that Dr. Rentoul states obtain in Government services, it is our misfortune and not our fault. At the present time the difficulty we are experiencing is being felt by almost every hospital in London. To use a colloquialism, residents are hardly to be obtained for love or money.

I am, Sir, yours faithfully,

W. M. WILCOX,
Secretary.

East London Hospital for Children,
Shadwell, E., Feb. 16th, 1915.

* * We regret the mistake. Voluntary help is being accorded to some hospitals in a similar dilemma, we understand, and medical men who are able to assist charitable work in this way are discharging a most valuable duty.—ED. L.

TYPHOID AND PARATYPHOID INFECTION IN RELATION TO ANTITYPHOID INOCULATION.

To the Editor of THE LANCET.

SIR,—Owing to an error in the delivery of the "proof" of the paper which you so kindly published for us last week at very short notice, two small errors remained uncorrected. On p. 325, col. 1, the second line from the bottom should read: "In non-inoculated persons," &c. As it stands the statement is obviously nonsense. On the same page, col. 2, line 35 (about the middle of the page), the figure 700 should be 900, as can be seen from the chart on the following page.

We are, Sir, yours faithfully,

GEORGES DREYER,
E. W. AINLEY WALKER,
ALEX. G. GIBSON.

Department of Pathology, University of Oxford,
Feb. 16th, 1915.

"WOOLNER'S TIP" AND FAMILY RESEMBLANCES.

To the Editor of THE LANCET.

SIR,—Apropos of the informing annotation on this subject in THE LANCET of Feb. 13th it may interest your readers to know that Thomas Woolner was probably careful to reproduce the "tip," named after him, in his well-known bust of Darwin now at Cambridge. At least, one may infer that he did so, as it may be felt, when searched for *ad unguem*, to use the old Roman sculptors' phrase, in the left ear of the plaster replica of this bust recently

placed between Huxley and Owen in the museum vestibule of the Royal College of Surgeons of England. The plaster bust, presented to the College by Sir Lauder Brunton, Bart., was executed in or after 1869, in which year Woolner sculptured the likeness of Darwin's head. It is not a very good likeness of the great naturalist, a better having probably been caught by Sir Lauder Brunton himself, whose model in clay after the engraving by Jeens in *Nature*, elicited the remark from Darwin, "Well! one never knows what one is like." The pose of this was absolutely correct: Woolner's was not, though Woolner has reproduced the Cro-Magnan brows of the great authority on earliest man. Darwin refers to the "celebrated sculptor, Mr. Woolner," in an early chapter of the "Descent of Man," which was published in 1871. Woolner became aware of the "little blunt point projecting from the inwardly folded margin or helix" when engaged on a bust of Puck. He sent a drawing showing the "tip" to Darwin, which the latter has reproduced in his text. In Woolner's marble bust of Sir John Simon, K.C.B., also at the College, the tip is plainly distinguishable, but it does not reappear in the plaster cast of the same. The older sculptors, such as Chantrey, executed the ear conventionally, if, indeed, they did not hide it under a fringe of hair. This appears on examination.

It is a question how far a sculptor should be a minute anatomist. The Greeks, as Professor Mahaffy points out, were eclectic, and sculptured "combination" limbs or organs, choosing the most shapely points from many models and thus combining an idealised type. This appears in their reproductions of the genital organs of man. M. Rodin, on the other hand, was so intent on reproducing the exact proportions and outlines of limbs, muscles, veins, &c., that he made of his Saint John a sort of squat anatomical model, suggestive of a man divested of underclothing. The statue when sent in competition to the Académie des Beaux Arts was rejected by the judges on the ground that it was a cast from nature—at least, so the legend runs.

With regard to family likenesses, I may mention that an ancestral type sometimes reappears in a surprising manner. The late Paul Fordyce Maitland, a landscape painter familiar some years ago to habitués of Kensington Gardens, might have been Maitland of Lethington returned to life, so strikingly did his fine face resemble that of his ancestor. The same may be said of a living descendant now in London of Mallet du Pan and of Juan Bonaparte. And I trust I am not guilty of impertinence when I say that Miss Hunter Baillie, when standing in front of G. Home's portrait of her illustrious collateral ancestor John Hunter, wearing a brown coat, appeared to interested observers as if she had stepped out of the frame.

Others besides myself may have observed that for one moment just after death a face seems sometimes to change back to the exact resemblance of some familiar family portrait or miniature.

I am, Sir, yours faithfully,

P. V.

Feb. 15th, 1915.

On Feb. 15th, at Bow-street police-court, Mr. Hopkins committed for trial at the Central Criminal Court Arthur Alfred Henry Bennett, described as a surgeon of no fixed abode, on the charge of committing perjury in the High Court of Justice in July last during the hearing of the action for libel unsuccessfully brought by Mr. C. H. Stevens against the British Medical Association.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE CENTRAL EXECUTIVE COMMITTEE.

A MEETING of the Central Executive Committee was held on Feb. 11th at the office of the British Medical Association, when Mr. J. Y. W. MacAlister, librarian and secretary of the Royal Society of Medicine, joined the meeting as a coöpted member of the committee. Correspondence between the chairman, Sir Rickman Godlee, and the President of the General Medical Council was read, showing the difficulty that there would be in securing any remission of, or reduction in the registration fees payable by Belgian graduates now admitted to the British Register under certain conditions. The committee therefore decided to act in accordance with the course of conduct previously decided upon, and the registration fees will be advanced by the Fund in cases where such action appears necessary and suitable, and where the Belgian graduates have received offers of employment.

Dr. Des Vœux took the occasion of the first meeting held since the money which had passed through the treasurer's hands exceeded £5000 to make a short financial statement. He said that £5297 had been received by him and acknowledged in *THE LANCET*, the *British Medical Journal*, and the pharmaceutical journals. More money than this had been subscribed, as certain local funds remained in the hands of the local treasurers, as did the Scottish and Irish Funds. Mentioning the principal subscriptions in detail, he said that so far money had only been received from 1500 people, allowing for the fact that certain large subscriptions had been sent to him with no epitomised details. He had placed £4000 on deposit at the bank, and showed that a sum of about £470 had been spent already, or was arranged to be immediately spent upon pecuniary relief in urgent cases, upon purchase of clothes, upon advances for registration fees, and upon boxes of medical material shipped to Brussels through the Commission for Relief in Belgium. The committee decided to carry on their work for the present upon the same lines, on the one hand helping immediately in necessary cases, and on the other husbanding the money as much as possible, after the relief of urgent distress, so that it may be available as the nucleus of a future international subscription for the rehabilitation of the medical profession in Belgium.

The committee, through the eleemosynary sub-committee, has made grants to certain urgent cases, either for the purchase of necessities like food and clothes, or to facilitate the taking up of paid appointments. The registration fees have also been paid of Belgian medical men who are joining the British Register preparatory to accepting salaried posts.

THE AMERICAN COMMITTEE FOR THE AID OF BELGIAN PHYSICIANS.

The treasurer of the committee of American physicians constituted for the aid of the Belgian medical profession has made a report of all contributions received up to and including Jan. 16th, 1915. A total of \$1,414 had been received by that date, including subscriptions of \$100 from Dr. Franklin H. Martin, Chicago; Dr. F. F. Simpson, Pittsburg; Mrs. John B. Murphy, Chicago; Dr. Abraham Jacobi, New York; and the Academy of Medicine, Cincinnati. The expenditure so far includes the

payment for 450 boxes of food purchased from Austin, Nichols and Co. at \$2.20 per box. Dr. F. F. Simpson, Jenkins Arcade Building, Pittsburgh Pennsylvania, is acting as treasurer to the committee, and has issued a circular stating that all contributions will immediately be converted into supplies and that these will be transmitted to Belgium and distributed among the Belgian doctors. The circular issued by Dr. Simpson and Dr. Howard C. Taylor, the secretary of the committee, says: "Every cent of every dollar contributed will be available for the purchase of supplies as the carrying charges are provided for by the American Commission for Relief in Belgium. The first one thousand dollars contributed have been expended by the Executive Committee for food and supplies, and the packages properly labeled have been started for their destination."

The personnel of the committee as now constituted is as follows: Victor C. Vaughan, President, American Medical Association; William L. Rodman (Vice-chairman), President-elect, American Medical Association; John B. Murphy, President, Clinical Congress of Surgeons of North America; Charles H. Mayo, President-elect, Clinical Congress of Surgeons of North America; J. M. T. Finney, President, American College of Surgeons; J. Riddle Goffe, President, Seventh International Congress for Obstetrics and Gynaecology; Stuart McGuire, President, Southern Medical Association; Samuel J. Meltzer, President, Association of American Physicians; Hugh Cabot, President, Mississippi Valley Medical Association; William C. Woodward, President, American Public Health Association; Theodore C. Janeway, Johns Hopkins Medical School, Baltimore; Frank Billings, Chicago; George H. Simmons, Editor, *Journal of the American Medical Association*; Franklin H. Martin (Chairman), Editor, *Surgery, Gynaecology, and Obstetrics*; Thomas L. Stedman, Editor, the *Medical Record*; E. W. Taylor, Editor, the *Boston Medical and Surgical Journal*; Claude L. Wheeler, Editor, the *New York Medical Journal*; Howard Canning Taylor (Secretary), New York; and Frank F. Simpson (Treasurer), Pittsburgh, Pennsylvania.

THE WEEK'S SUBSCRIPTIONS.

The subscriptions received by Dr. Des Vœux up to Tuesday evening last, in addition to those previously acknowledged, and not including money collected by certain local funds, and the Scottish and Irish Funds, are as follows:—

	£ s. d.		£ s. d.
Dr. Sheila M. Ross ...	1 1 0	Brussels Medical Graduates' Association (per Dr. Major Greenwood, Treas.), further donation ...	6 6 0
Mr. G. Grahame, H.M. Consul-General ...	1 1 0	Miss C. M. Lacey ...	1 1 0
Dr. Edgar F. Cyriax ...	3 3 0	Jersey Medical Society (per Mr. E. O. B. Voisin, Treas.) ...	5 5 0

		Mr. G. H. Toy (per Mr. F. Smith, Hon. Sec. Birmingham Pharmaceutical Association) ...	0 10 0
		Mr. A. Pellew ...	1 1 0

The Western Pharmacists' Association head the list with the handsome donation of £120, and £100 have been received from the Nurses' General Hospital, Rangoon.

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund and crossed Lloyds Bank, Limited. These will be acknowledged by post direct, and a list will appear in THE LANCET weekly.

A WATER SCARE IN LONDON.—Water consumers in the west-end district of London were somewhat alarmed early in the week to find that their service-supply was offensive both to the taste and smell. We understand that an official assurance has been issued to the effect that the unpleasant condition of the water was due to harmless algae—water organisms of no pathogenic significance whatever. Two years ago the same thing happened in the Hampstead district without any harm accruing. The alarm was intensified in the recent instance by a suggestion that possibly the reservoirs had been tampered with by our enemies. We wonder whether this departure from the normal condition of our water-supply was possibly connected with the flooding of the Thames a month or so ago. We then remarked that "it will be interesting to watch the future official reports upon the purity of the supply based upon the examination of samples synchronising with the flooding period." Consumers are perfectly justified in refusing to use an offensive water until the circumstances are cleared up, but in the meantime they would be safeguarded by adopting the simple precaution of boiling the water, when its disagreeableness would disappear and all questions of its possible pathogenicity dispersed.

The War.

MENTIONED IN DESPATCHES.

The following officers connected with the medical profession and occupying the indicated positions with our army are recommended in Sir John French's despatch, dated Jan. 14th and issued from the War Office this week, "for gallant and distinguished service in the field." Alas, several of them are no longer with us.

THE CASUALTY LIST.

The casualties among officers in the Expeditionary Force reported from General Headquarters since our last issue include the name of Surgeon-Major Robert Macnamara Cowie, 1st Life Guards, wounded.

THE CONTROL OF ENTERIC FEVER AT HOME.

The War Office, after consultation with the Local Government Board, have decided that a special record is to be kept by military sanitary officers concerning each case of enteric fever occurring amongst soldiers in this country. The objects in view are (1) to ensure that each case is made the subject of inquiry; (2) to provide material for further inquiry where multiple cases occur; (3) to compare the experience of various military units; and (4) to enable a summary to be prepared of the experience of the army as a whole and in different parts of it.

Under the arrangements already made military medical officers are required to inform the medical officer of health of the sanitary district in which troops are stationed of any cases of enteric fever which may occur, and it is important that the medical officer of health should coöperate with these officers and with military sanitary officers in tracing the source of infection and removing any conditions favouring spread of the disease. The medical officer of health will be in a position to give information as to the relationship of each case to causes of infection present in his district, or, if the infection has been contracted elsewhere, to communicate on the subject with the medical officer of health of the district concerned. The War Office and Local Government Board have agreed upon a method of procedure in regard to the forms of record, which can be obtained by medical officers of health of sanitary districts on application to the Local Government Board.

THE COMMANDER-IN-CHIEF ON THE WORK OF THE R.A.M.C.

Field-Marshal Sir John French in his latest despatch pays the following tribute to the medical service of the British Expeditionary Force:—

Since the commencement of hostilities the work of the Royal Army Medical Corps has been carried out with untiring zeal, skill, and devotion. Whether at the front under conditions such as obtained during the fighting on the Aisne, when casualties were heavy and accommodation for their reception had to be improvised, or on the line of communications, where an average of some 11,000 patients have been daily under treatment, the organisation of the medical services has always been equal to the demands made upon it. The careful system of sanitation introduced into the army has, with the assistance of other measures, kept the troops free from any epidemic, in support of which it is to be noticed that since the commencement of the war some 500 cases only of enteric have occurred.

The organisation for the first time in war of motor ambulance convoys is due to the initiative and organising powers of Surgeon-General T. J. O'Donnell, D.S.O., ably assisted by

Major P. Evans, Royal Army Medical Corps. Two of these convoys, composed entirely of Red Cross Society personnel, have done excellent work under the superintendence of regular medical officers. Twelve hospital trains ply between the front and the various bases. I have visited several of the trains when halted in stations, and have found them conducted with great comfort and efficiency. During the more recent phase of the campaign the creation of rest depôts at the front has materially reduced the wastage of men to the line of communications.

Since the latter part of October, 1914, the whole of the medical arrangements have been in the hands of Surgeon-General Sir A. T. Sloggett, C.M.G., K.H.S., under whom Surgeon-General T. P. Woodhouse and Surgeon-General T. J. O'Donnell have been responsible for the organisation on the line of communications and at the front respectively.

THE BRITISH RED CROSS SOCIETY.—The summary of the work for the week ending Feb. 13th states that since the last report ambulances have been despatched to Dunkirk, Boulogne (2), and Havre (3). A touring car has been sent to Calais. The number of hospitals accepted by the War Office to date is 759, containing beds for 20,771, including 210 beds accepted during the past week.

THE HEALTH OF THE NAVAL DIVISION.—The following announcement was made this week by the Secretary of the Admiralty: Rumours in circulation that the general health of the Naval Division in training at the Crystal Palace is unsatisfactory are quite inaccurate. Cases of serious illness of every kind are bound to occur in any large body of men like that of the Naval Division, but on the whole the health of the men has been and is excellent, and there is no reason to anticipate any deterioration in this respect. Out of 8000 men the average sick list is under 150, or less than 2 per cent.

SOLDIERS' AND SAILORS' DENTAL AID FUND.—The objects of this fund are the conservation of the teeth of soldiers and sailors who are already in the Services, and the provision of dental treatment for recruits with defective teeth. Reports both here and from the front testify to the good work which has been done. An appeal for subscriptions which has been issued by the committee should therefore meet with a ready response, and Queen Alexandra has shown her appreciation of the work by heading the subscription list. All the work is voluntary, the Fund pays for artificial teeth, and the dental departments of hospitals and dental surgeons do the filling, extraction, fitting, and so forth. It may be pointed out that at one dental hospital alone 4000 patients were treated from September to December last year, and it is estimated that quite 6000 require to be dealt with immediately. Lady Frederick Conyngham is the honorary secretary, and the address of the Fund is 36, Leicester-square, London, W.C.

SCOTTISH AMBULANCES FOR THE FRONT.—Our Edinburgh correspondent writes: "In order to meet the needs of the great armies being sent from this country to France, and so that the suffering of the sick and wounded may receive the promptest possible care and attention, strenuous efforts are being made by the Red Cross Society to place at the disposal of the War Office an adequate supply of ambulance wagons. That Red Cross workers in Edinburgh and district have been putting their best foot foremost was shown by the splendid 'turn out' last week of fully equipped motor ambulances destined for the front, which paraded the streets and were inspected by Lord Provost Inches. The cars on parade numbered nine, and were part of a convoy of 50 ambulances, motor cycles, and staff cars which are being handed over to the Scottish Branch of the Red Cross Society to the War Office, and which are to proceed to the front as a Scottish column at an early date."

THE SCOTTISH MOTOR AMBULANCE COLUMN.—Our Edinburgh correspondent refers above to the contribution by the Scottish capital towards the gift of motor ambulances from the people of Scotland to the War Office. On Feb. 17th the King inspected the full column of 62 vehicles at Buckingham Palace, and a luncheon was held at the Royal Automobile Club to signalise the event. Sir George T. Beatson, K.C.B., M.D., chairman of the Scottish Branch of the British Red Cross Society, presided over the gathering,

and was supported among others by the Duke of Buccleuch, the Hon. A. Stanley (chairman of the executive committee of the British Red Cross Society), Surgeon-General M. W. Russell, A.M.S., and Major Fleming (secretary of the Scottish Branch). The record of the Scottish branch during the war is one of which Scotland may well be proud. All classes have contributed in money or in kind, and the total war fund raised is now over £140,000, of which £80,000 has been devoted to the purchase and upkeep of motor ambulances at the seat of war. Out of the funds 91 ambulance cars have already been provided.

ABERDEEN AND THE WAR.—Our local medical correspondent writes: "Altogether some 2900 wounded soldiers and sailors have been treated in the Aberdeen hospitals, about 380 being Belgian soldiers. In addition to this, between 500 and 600 local soldiers have been treated at the hospitals.—The Aberdeen Burgh Panel Committee have issued a circular to the medical practitioners in Aberdeen regarding the proposed establishment of a central bureau in connexion with the carrying on of the work of service practitioners. The proposed scheme is to have a central bureau to which all calls are to be sent, these calls to be allocated by the bureau amongst civil practitioners who may agree to do the work, always keeping in view as far as possible that practitioners should have their calls in the districts in which they reside. All fees would be collected by the bureau, and after deducting expenses, half would go to the service practitioner and the remaining half to the practitioner who had done the work. If necessary, a central consulting-room would be established. It is proposed that both panel and private practice should be undertaken by the bureau, and the freedom of choice of a doctor would, as far as possible, be given to patients."

ABERDEEN ROYAL INFIRMARY AND THE WAR.—At the annual general meeting of the corporation of the Aberdeen Royal Infirmary and Lunatic Asylum the chairman, Mr. Alexander Duffus, in moving the adoption of the report, said that the year's work had been carried out under very exceptional circumstances. At one time it looked as if the medical and surgical staff would be reduced to one, all the others being mobilised and either away from Aberdeen on service or not available, owing to the claims on them for duty in military hospitals in town. Fortunately, however, an arrangement was come to with the military authorities under which a certain number of the medical and surgical staff were enabled to attend, to a reasonable extent, daily to infirmary work. In August last, in response to a request from the Admiralty, arrangements were made to provide for a certain number of naval casualties. As yet that accommodation has not been required, though 69 cases of naval sick have been treated. When the pressure upon military hospitals in Aberdeen was very great arrangements were made for 50 beds to be available for the more serious of military wounded, and in all 227 soldiers have been admitted and dealt with as infirmary patients. While doing what they could to help, the directors made every effort to safeguard the claims of the civil population for whom the infirmary exists. Thanks were extended to Mr. Scott Riddell, who kindly agreed to act as honorary superintendent when Dr. W. Sinclair was mobilised, also to Miss Edmondson, the matron, for her valuable services at this time. The chairman also congratulated all three senior surgeons of the infirmary, Mr. Riddell upon his services as Red Cross Commissioner for the North of Scotland, Professor J. Marnoch upon the distinction of C.V.O. conferred upon him by His Majesty the King, and Mr. H. M. W. Gray upon his appointment to the post of one of the consulting surgeons at the front.

KING MANOEL AND WOUNDED OFFICERS.—King Manoel is generously providing through the British Red Cross Society a home for wounded officers, and for this purpose Admiral the Hon. Sir Hedworth Meux, Naval A.D.C. to the King and Commander-in-Chief at Portsmouth, has lent his Brighton house. The house is situated at Kemp Town, commanding a fine sea view, and arrangements are being carried out with a view of receiving as many convalescent officers as it will accommodate. King Manoel and Sir Frederick Treves, on the occasion of a recent visit to the town, visited the Indian General Hospital at the Royal Pavilion and inspected the premises of the new hospital.

THE FRENCH RED CROSS.—A letter in another column from Dr. James Donelan explains the organisation of the London branch of the French Red Cross. On the initiative of the French Ambassador this branch of the French Red Cross Society has now been placed under the presidency of the Vicomtesse de La Panouse, the wife of the French Military Attaché. This branch will henceforward be the only representative in London of the union of the three Red Cross societies established in France. An honorary and an executive committee have been formed. The honorary committee is composed of Queen Alexandra, Monsieur Paul Cambon, the French Ambassador, the Duchess of Norfolk, the Duchess of Somerset, and many other influential people. The following constitute the executive committee:—President, Vicomtesse de la Panouse; vice-president, Madame Brasier de Thuy; treasurer general, Comtesse de Saint Seine (wife of the French naval attaché); secretary general, Madame Phalempin. The treasurer is Mrs. N. Lake, the honorary secretaries are Mr. P. A. Wilkins and Mr. C. J. Baker, and the medical referee is Dr. James Donelan. The committee's offices are at 25, Knightsbridge, London, S.W.

AN ENTERIC HOSPITAL FOR CALAIS.—The joint war committee of the British Red Cross Society and the Order of St. John of Jerusalem recently undertook to provide at Calais an enteric hospital of 156 beds for the exclusive use of Belgian soldiers. The complete hospital has now been built in this country and transported to Calais in the short period of three weeks, and it is being set up there by 100 workmen sent over from this country. The hospital consists of six wards of 26 beds each, and is completely equipped. It includes, in addition to the wards, separate nurses' accommodation, a dispensary, a disinfectant, a destructor, kitchens and orderlies' barracks, steam laundry, dining hall, and other necessary offices. Supplies of drugs have been despatched from the Red Cross Stores, 83, Pall Mall, together with sterilisers, disinfecting plant, beds and bedding, &c. The hospital and its equipment represent 500 tons of material. This was sent by rail to Dover by five special goods trains and transferred thence to Calais by special Admiralty transport boat. The workmen sent over to erect the hospital were all insured and inoculated, and special housing accommodation and feeding arrangements were made for them before their arrival. The planning and construction in so short a period of this complete hospital reflect much credit upon the stores department of the joint Red Cross committee.

THE AUTOMOBILE ASSOCIATION FRENCH AMBULANCE FUND.—Early in October last it came to the knowledge of the executive committee of the Automobile Association and Motor Union that while the British military authorities were being well supplied with motor ambulances, the French army was sadly lacking in this respect. An appeal was accordingly sent out in November asking members for (1) entire ambulances, (2) cars suitable for conversion into ambulances, and (3) subscriptions towards providing the necessary ambulance bodies, &c. The association then communicated with the Service de Santé de Gouvernement Militaire de Paris, and as a result, on Oct. 27th promised as a first instalment a free gift of 50 ambulances. The response to this appeal has been generous, 230 cars having been offered to the committee. Thirty-eight have already been sent to France, and the second contingent numbers 55. Nearly 1000 members unable to provide cars contributed cash subscriptions totalling over £6000. The cars as offered have been collected by road and rail from all parts of England, Scotland, Ireland, and Wales. The engineering department of the "A. A." has supervised the work of converting and equipping the vehicles for their employment on the battlefield. On Feb. 11th a luncheon was held at the Savoy Hotel to celebrate the despatch of these motor ambulances to France, and subsequently the 55 cars were inspected at Buckingham Palace by the King.

QUEEN'S UNIVERSITY OF BELFAST AND THE WAR.—A roll of honour, compiled by authority of the Senate, has just been published, giving a list of those connected with the University who have served their country in the war and of those who are still fortunately able to act in this way. Among the five killed in action there is one medical officer, Captain T. M. Phillips, R.A.M.C., who died from a shell injury received at Ypres.

BRIGHTON AND HOVE MEDICAL PREPARATIONS AGAINST AIR RAIDS.—Referring in our last issue to the medical preparations against possible air raids on London we stated that with the sanction of the military and police authorities the London scheme had now been elaborated and extended to include vulnerable places on the coast. We have received a copy of the very complete scheme organised by the borough councils of Brighton and Hove, which will bear the cost thereof. In these towns 29 dressing stations having telephonic communication have been established. The organised personnel consists of 78 out of 90 civilian doctors who have volunteered their services gratuitously, a staff of nurses, stretcher-bearers with stretchers from the Home Protection Brigade, and 320 boys from various boys' organisations to act as messengers, or cyclists. The medical man in charge of each dressing station is given authority to arrange the equipment of his station in accordance with his requirements. Each doctor is also supplied with emergency dressing packages. The medical men have been assigned to their allotted stations. Fourteen nursing homes have agreed to receive the surplus injured should they be in excess of those whom the hospitals can accommodate.

ENLARGEMENT OF THE SECOND EASTERN GENERAL HOSPITAL, BRIGHTON.—At the beginning of the war this hospital was mobilised with its arranged number of beds—namely, 520. Since then it has been gradually extended, and now has 1000 beds available. There are five blocks composing the hospital, three surgical and two medical. The former are as follows: The new Brighton and Hove Grammar School in the Dyke-road and the Howard Convalescent Home and St. Mark's Council School at Kemp Town. The medical blocks are at Stanford-road Council School and at Lewes-crescent, Kemp Town. The staff has been augmented, consisting now of about 30 medical and surgical officers. Several thousand patients have already been treated at the different branches, both men from the Expeditionary Force and men from the many large camps in the neighbourhood. There are four operating theatres, at all of which various operations are constantly being performed. A great number of these are on men who have not yet been to the front, but who require some operative procedure to fit them for active service.

LIVERPOOL DOCTORS AND ANTITYPHOID INOCULATION.—At a largely attended meeting of medical practitioners at the Liverpool Medical Institution last week the question of antityphoid inoculation in the army was discussed, and a forcible paper on the subject was read by Professor Ernest Glynn, of which an abstract was sent to the local press. The following resolution was proposed by Captain W. Permewan, R.A.M.C. (T.), and seconded by Lieutenant-Colonel Sir James Barr, R.A.M.C. (T.), and carried unanimously:—

This meeting of the Liverpool Medical Institution expresses its strong conviction that the time has come to make antityphoid inoculation compulsory in the British Army.

A WATER-STERILISING OUTFIT.—We have received from Messrs. Burroughs, Wellcome, and Co. specimens of tabloids of chlorinated lime and sodium thiosulphate together with solids of potassium iodide and starch. The whole forms an easily portable outfit for the certain sterilisation of water. The procedure is very simple. As a starting point 1 tabloid water steriliser (chlorinated lime) is dissolved in 10 gallons of water, the mixture being allowed to stand for 15 minutes. Then, to ensure that sufficient of the steriliser has been used, a test is made in the following way. A little of the water is placed in a cup or other vessel in which has been placed one soloid containing potassium iodide and starch. If a blue colouration occurs there is an excess of chlorine present and the work of sterilisation is complete. Otherwise another tabloid steriliser must be added until the presence of free chlorine is shown by the soloid potassium iodide starch test. The excess of chlorine is then removed by adding one tabloid of sodium thiosulphate for each tabloid of steriliser and the water becomes fit for drinking and palatable. This is a very ingenious and simple method and should be of the greatest value in a campaign.

It is reported by the Berne correspondent of the *Times* that Dr. Philipp Peck, head of the Austrian Army Medical Staff, has died from "spotted typhus."

Obituary.

ROBERT BURNET, M.Sc., M.B., CH.B. VICT., M.Sc.,
M.B., CH.B. LIVERP., D.P.H. BIRM.,
MEDICAL OFFICER OF HEALTH OF CORNWALL; LIEUTENANT-COLONEL,
ROYAL ARMY MEDICAL CORPS (T.).

Lieutenant-Colonel Robert Burnet, R.A.M.C. (T.) was killed in Devonshire recently by being thrown from his horse.

Robert Burnet received his professional education at University College, Liverpool. In 1897 he took the B.Sc. at Victoria University with first-class honours and a scholarship, in 1900 the M.B., B.Ch., and in 1901 the M.Sc. In 1902 he was appointed district medical officer of the parish of Birmingham. In 1904 he was admitted to the M.Sc., M.B., and B.Ch. of Liverpool University, and in 1908 he took the D.P.H. at the University of Birmingham. Three months later he was appointed medical officer of health of the county borough of Bury, Lancs., and shortly afterwards superintendent of the large combined isolation hospital there. He developed the work of inspection instituted by his predecessor, Dr. Brindley, and assisted in the establishment of a municipal hospital for tuberculosis. In 1910 he was appointed county medical officer of health of Cornwall. Dr. Burnet took a keen interest in military medical matters. In 1908 he joined the R.A.M.C. (T.) at Handsworth, Staffs., was transferred on going to Bury to the Lancashire Fusiliers, and was again transferred on going to Cornwall, when he was promoted to the rank of lieutenant-colonel.

Dr. A. H. Bygott, of Bury St. Edmunds, writes: "I first met Robert Burnet in 1902, soon after his appointment as district medical officer of the parish of Birmingham, and have been very intimately connected with him ever since. The appointment was remarkable, as the result of a determined attempt by an enlightened board of guardians to organise their outdoor medical department on the best possible lines by availing themselves of whole-time officers at a substantial salary. Dr. Burnet took an especially keen interest in this work and did his best to develop it, but that he felt he had undertaken a practically impossible task is shown by his evidence before the Royal Commission on the Poor-laws, in 1907, in which he suggested that the medical services controlled by the boards of guardians should be transferred to the public health authorities. This policy was adopted in the Minority Report, and he continued to support it on every available occasion. During Dr. Burnet's first year of office as medical officer of health of Cornwall there was a very serious epidemic of poliomyelitis in the county, in the investigation of which he proved himself indefatigable, but in connexion with which he sustained a very serious blow. His only son, a brilliant boy who was destined for the navy, fell a victim to this disease, and though his life was spared after a very serious illness, he was left hopelessly paralysed. Dr. Burnet's early career was a brilliant one. He was a man of varied talents, and possessed no mean gifts as an artist and musician, though the strenuous life that he led in latter years left him scant leisure for them. He was singularly alert, and threw himself with ardour into every detail of whatever he undertook. He was also one of the most conscientious men that I have ever known. A host of friends will mourn their loss, and the deepest sympathy will be felt for his young widow and his children."

PATRICK JOSEPH MACNAMARA, M.D. R.U.I.,
F.R.C.S. IREL.,
CHAIRMAN OF THE IRISH MEDICAL COMMITTEE.

THE death of Dr. Patrick Macnamara, of Kilmallock, co. Limerick, occurred on Feb. 4th after a few days' illness. He was one of the most representative of Irish country doctors, and his unanimous election on two occasions as chairman of the Irish Medical Committee was a striking proof of confidence in his ability and fairness.

Dr. Macnamara was educated at Cork and Dublin, and became M.D. of the Queen's University and Licentiate of the Royal College of Surgeons in 1872. Fifteen years later he proceeded to the Fellowship of the College. His entire professional life was spent in his native county of Limerick, where for many years past he was a justice of the peace for the county and medical officer of the Kilmallock workhouse. While undertaking all the arduous duties of a country practitioner in Ireland he spared no pains to keep himself abreast of knowledge in medicine, surgery, and midwifery, and in his workhouse hospital he did surgical work of excellent quality. He acquired a reputation in many branches of practice which made his opinion much in request as a consultant and helped him to occupy an important place in public esteem in the south of Ireland, an esteem to which his high personal character contributed largely.

He was for many years an active member of the council of the Irish Medical Association. When, in 1913, the Conjoint Committee, which had up to that time represented Irish medical interests in reference to the National Insurance Act, was dissolved, Macnamara was chosen chairman of the newly constituted Irish Medical Committee. The moment was a critical one for the profession, for the committee contained some very discordant elements, and if a split had occurred all hope of unity in the profession would have vanished. But Macnamara, by his forbearance, tolerance, perfect courtesy, and occasional humour, kept in good temper the meetings over which he presided, and thus placed the profession of Ireland under a debt to him.

JOHN DEE SHAPLAND, M.R.C.S. Eng., L.S.A.

By the recent death of Mr. John Dee Shapland Exmouth has lost an old resident who witnessed its growth from a comparatively small size to its present dimensions and who was for many years actively engaged in general practice there, being district medical officer from 1891 to 1905.

John Dee Shapland was born at North Molton in North Devon on Nov. 30th, 1839, and was educated at South Molton and Axminster. On leaving school he was articled to Dr. Forrester at Barnstaple, where he remained but a very short time. He then went to University College Hospital, when the medical staff included Jenner, John Erichsen, Sharpey, Quain, and Ellis. After qualifying as M.R.C.S. in 1861 he was for a time assistant to a practitioner in Watford, and later settled in general practice at Thornton Heath, becoming medical officer for the union of Croydon. He left that neighbourhood for North Devon in 1882, settling first at Downrew, near Bishop's Tawton, and removing thence to Burnside, Withycombe, Exmouth, where he resided until his death. A keen sportsman and horticulturist, he was also a good practitioner, and to the end of his working life kept himself well abreast of modern scientific developments.

MICHAEL MCHUGH, M.A., M.D. DUB.,
L.R.C.P. & S. IREL.,

PROFESSOR OF MATERIA MEDICA IN THE SCHOOL OF THE ROYAL
COLLEGE OF SURGEONS IN IRELAND.

THE death of Professor McHugh occurred quite unexpectedly on Jan. 8th. He had been about his work as usual on the 7th, but was found dead in bed next morning, death having apparently taken place some hours previously. He was only 58 years of age.

Michael McHugh was educated in Trinity College, Dublin, and afterwards at Berlin and Vienna. He was for many years one of the visiting physicians to St. Vincent's Hospital and the Cork-street Fever Hospital, Dublin, and since the death of Sir George Duffey he had been professor of materia medica and therapeutics in the School of the Royal College of Surgeons. He had been an external examiner in medicine at the University of Dublin, and examiner in medical jurisprudence at the Royal University of Ireland. He had a high reputation as a scientific physician, and although of a retiring disposition, was held in great regard by his pupils and colleagues.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of Comitia of the Royal College of Physicians of London on Jan. 28th and of the Council of the Royal College of Surgeons of England on Feb. 11th diplomas of L.R.C.P. and M.R.C.S. were conferred respectively upon 114 candidates (including three ladies) who have passed the Final Examination in medicine, surgery, and midwifery of the Conjoint Board and have complied with the requisite by-laws. The following are the names and schools of the successful candidates:—

Christie Muthuswamy Anthony, Guy's Hospital; Mary Elizabeth Ashton, Calcutta, Manchester University, and Royal Free Hospital; Errington Atkinson, London Hospital; Geoffrey Lewis Atwater, Cambridge University and Guy's Hospital; James Dorrington Bangay, St. Bartholomew's Hospital; Percy William Barnden, London Hospital; Burgess Barnett, St. Bartholomew's Hospital; Kanshi Ram Batra, University College Hospital; Owen Albert Beaumont, Cambridge University and London Hospital; Arthur Leslie Blunt, St. Thomas's Hospital; Harold Esmond Arnison Boldero, Oxford University and Middlesex Hospital; Johannes Willem Bouwer, London Hospital; Leonard Graham Brown and Charles Milwyn Burrell, Oxford University and London Hospital; Harold George Bywater, Liverpool University; Rowland Burnell Campion, Guy's Hospital; Maurice Hereward Cane, Cambridge University and St. Bartholomew's Hospital; Dorothy Chick, Royal Free Hospital; William King Churchouse, Charing Cross Hospital; Joseph Woods Clayton, Adelaide University and London Hospital; Philip Cyril Powter Cloake, London Hospital; William Lonsdale Cockcroft, Manchester University; Stephen Walter Coffin, Guy's Hospital; Dora Challis Colebrook Royal Free Hospital; Ernest James Cooke, Guy's Hospital; Edward Charles Cunningham, Cambridge University and St. Bartholomew's Hospital; Eric David Despard Davies, Cambridge University and St. Mary's Hospital; Alexander Decimus d'Avray, University College Hospital; George Stanley Deane and Cedric Roland Denny, London Hospital; Charles Wilmot Dias, Ceylon Medical College and St. Mary's Hospital; Herman Gerald Dresing, Copenhagen University and Guy's Hospital; Albert John Kingman Drew, Guy's Hospital; Sidney Ernest Elphick, St. Mary's Hospital; Ahmed Zaki Elsayed, Cairo and London Hospital; James Fanstone, London Hospital; Harry Hope Fisk, St. Mary's Hospital; George Muir Foster, Bristol University and University College Hospital; Lewis Salisbury Fry, Cambridge University and Guy's Hospital; Alec Terris Gibb, Manchester University; John Wesley Gilbert, Bristol University; Edmund Douglas Granger, St. Thomas's Hospital; Stanley Willoughby Green, Leeds University; Norman Grellier, Charing Cross Hospital; Herbert Stuart Griffith, St. Bartholomew's Hospital; Douglas Noel Hardcastle, St. Mary's Hospital; William Theodore Hare, Cambridge University and St. Thomas's Hospital; Frank Cecil Harrison, Sheffield University; Hugh Granville Hockridge, St. Bartholomew's Hospital; Lancelot Horsley, Guy's Hospital; Ifan Septimus James, University College Hospital; William Baly Jepson, St. Bartholomew's Hospital; Cyril Oscar Howe Jones, Middlesex and St. Thomas's Hospitals; Dadabhai Nowroji Kalyanvala, Bombay University and University College Hospital; Charles George Gordon Keane, St. Mary's Hospital; Felix Edward Ricardo Laborda and Stephen Abraham Liebson, Guy's Hospital; Neville Hood Linzee, London Hospital; Percy East Lones, University College Hospital; William Francis MacAlevy,

St. Mary's Hospital; Cecil Granville McClymont, Guy's Hospital; James McDonnell, London Hospital; Edmund Claud Malden, Cambridge University and King's College Hospital; George Allan Maling, Oxford University and St. Thomas's Hospital; Robert Charles Matson, Guy's Hospital; Eric Spanton Mawe, Cambridge University and St. Bartholomew's Hospital; Stanley Howard Miles, Cambridge University and St. Thomas's Hospital; Donald Samuel Eccles Milligan and William Hubert Milligan, St. Thomas's Hospital; Arthur Daniel Morris, University College, Cardiff, and University College Hospital; Herbert Guy Moser, St. Bartholomew's Hospital; Drevor Frederick Acton Neilson, Cambridge University and St. Thomas's Hospital; Kenneth Montague Nelson, St. Mary's Hospital; Charles Cyril Okell, Cambridge University and St. Bartholomew's Hospital; James Hales Parry, Cambridge University and Guy's Hospital; Owen Guy Parry-Jones, Oxford University and Guy's Hospital; Sachchidananda Hosen Paul, Calcutta University and Charing Cross Hospital; Hugh Ley Puxon Peregrine, King's College and Guy's Hospitals; Danwattage Don Philip Perera, Ceylon Medical College and University College Hospital; Haydn Peters, Charing Cross and Middlesex Hospitals; George Robinson Pirie, Toronto University; Kenneth Playfair, Cambridge University and King's College Hospital; Guy Algernon Pratt, Guy's Hospital; Oliver Beakley Pratt, Oxford University and St. Bartholomew's Hospital; Noel Parry Price, Guy's Hospital; Wilfrid Raffle, Cambridge University and London Hospital; Reginald Thompson Raine, Cambridge University and St. Thomas's Hospital; William Leonard Elliot Reynolds, Guy's Hospital; William Kenneth Armstrong Richards, Bristol University; James Albert Robinson, St. Bartholomew's Hospital; Alan Filmer Rook, Guy's Hospital; Harold Arthur Rowell, St. Thomas's Hospital; Arthur Paul Saint, Cambridge University and London Hospital; Noel Humphrey Wykeham Saw and Roland Sells, Guy's Hospital; Henry Richard Sheppard, St. Thomas's Hospital; William Sowerby, University of New Zealand and Middlesex Hospital; Harold Douglas Livingstone Spence, Queen's University, Kingston, and St. Bartholomew's Hospital; Alan Edward Staffurth, Cambridge University and St. Thomas's Hospital; William Fletcher Stiell, St. Thomas's Hospital; Lionel Frederick Strugnell, St. Bartholomew's Hospital; Charles Putnam Symonds, Oxford University and Guy's Hospital; Gordon Stuart Terry, Bristol University; Edgar William Todd, Cambridge University and St. Thomas's Hospital; Myles Denison Boswell Tonks, London Hospital; Oscar Ramsay Unger, University College Hospital; Algernon Randolph Upton, Birmingham University and St. Bartholomew's Hospital; Cedric Norman Vaisey, Bristol University; Joseph Stephen Wallace, University College Hospital; Philip Pennefather Warren, London Hospital; Robert Harvey Williams, St. Bartholomew's Hospital; Samuel Wilson, Guy's Hospital; Frank Hamersley Woods, St. Bartholomew's Hospital; and Henry Wardel Snarey Wright, University College Hospital.

Diplomas in Public Health were also conferred upon the following six candidates:—

Kishori Lal Chandry, Lahore Medical College and University College; Noormahomed Kasembhai Chohan, Bombay and Cambridge Universities; Herbert William Frankhauser, Melbourne University and Royal Institute of Public Health; Thomas Marlin, Glasgow University and University College; Lucy MacBean Ross, Glasgow University and University College; and Andrew James Shinnie, Aberdeen University and University College.

UNIVERSITY OF OXFORD.—The examination for the Diploma in Ophthalmology will commence on July 19th, and for the Diploma in Public Health June 1st. The Board of the Faculty of Medicine gives notice that the Certificates in Anæsthetics (No. 11), Practical Pharmacy (No. 12), and Practical Pharmacology (No. 13) will be accepted on the old forms (see Examination Statutes, p. 232, ed. 1914) at all examinations held before Michaelmas Term, 1916. At the examination in Michaelmas Term, 1916, and afterwards only the new forms of certificate will be accepted.—The following medical degrees have been conferred:—

D.M.—H. P. Newsholme, Balliol.
B.M.—G. W. Carrington, Keble (*in absentia*).

PHARMACEUTICAL SOCIETY.—At the February meeting of this society two useful papers recording the results of experiments conducted in the society's research laboratories were communicated. In one of these Professor H. G. Greenish dealt with the problem of the discolouration of sodium salicylate solution by alkalies, a subject which, with Mr. A. E. Beesley as collaborator, he has recently investigated. The fact that a solution of sodium salicylate to which sodium bicarbonate has been added gradually assumes a brownish colour, deepening to dark brown or nearly black, is known to most medical practitioners and to all pharmacists, but it has never been definitely known to what this is due. Mixtures containing these two salts are frequently prescribed, and the matter is therefore of practical interest. It would seem that the discolouration is due to the oxygen of the air acting on the salicylate in the presence of sodium sesquicarbonate, and that the addition of about a grain of sodium sulphite or bisulphite to an ordinary 8 oz. mixture produces a marked preservative effect. Apparently there can be no possible objection to the use of this expedient. In the other paper Professor H. L. Smith

dealt with acetylsalicylic acid, which is one of the drugs that were formerly manufactured almost exclusively in Germany, but are now being made in this country by several manufacturers. Doubt has been expressed by some medical men and others as to the identity of the various makes of acetylsalicylic acid, and especially as to their identity with aspirin, and statements are sometimes made that one sample or another causes secondary effects, such as irritation of the stomach. Except that aspirin differs somewhat in appearance from the acetylsalicylic acid manufactured in Great Britain (aspirin crystals occurring in glistening flakes whilst the others appeared needle-like in form) most of the samples examined were identical with aspirin—that is to say, their chemical composition was the same. The question of the crystalline character is apparently of no particular importance, and Professor Smith's conclusion is that acetylsalicylic acid may be obtained without difficulty, chemically pure, from more than one source, but that, as with other chemicals, indifferent and impure makes are on the market, and therefore the same discrimination should be used in buying it as with other drugs.

THE Mayor of Sunderland has received from a number of medical practitioners of that borough upwards of £230 towards the local contribution to the Prince of Wales's National Relief Fund. This sum represents fees received for the medical examination of recruits.

TYPHUS FEVER IN LONDONDERRY.—Eleven cases of typhus fever have been notified, of which six occurred in one family. The origin of the outbreak has been traced to a "wake" held on Dec. 19th, 1914, at which crowds of persons attended, and all those suffering from typhus fever, with the exception of the district nurse, were present. Every precaution has been taken to stamp out the epidemic, but in addition to other causes of the disease, the district in which the outbreak occurred is almost uninhabitable in consequence of its bad sewerage.

DONATIONS AND BEQUESTS.—The late Miss Jane Osborn has left by will £500 each to the Great Northern Central Hospital and the Central London Ophthalmic Hospital; part of the residue of the estate will go to the Cancer Hospital, Fulham.—By the will of the late Mr. George Hepworth, of Castleford, Yorks, the Clayton Hospital, Wakefield, will receive £500 and the Wakefield City Deaf and Dumb Society £250.—Two donations have been intimated to the Dundee Infirmary, one of £500 from Mr. Andrew Scott with the proviso that only the income should be used and that two cots in the infirmary should be named, and the other of £1000 North British Railway Stock (Ordinary Preference) from Mr. J. J. Watson, Broughty Ferry, the interest only to be used.

UNIVERSITY OF LONDON.—At the last meeting of the Senate the titles of professor and reader in the University of London were conferred upon various teachers of the University on the recommendation of the respective boards of advisers. Mr. J. E. S. Frazer, St. Mary's Hospital, was made professor of anatomy; Dr. T. M. Lowry, Guy's Hospital, professor of chemistry; Dr. W. J. R. Simpson, King's College, professor of hygiene and public health; Mr. Major Greenwood, jun., Lister Institute, reader in medical statistics; Dr. R. G. Hebb, Westminster Hospital, reader in morbid anatomy; Dr. R. T. Leiper, London School of Tropical Medicine, reader in helminthology; Dr. F. S. Locke, King's College, reader in physiology; Dr. H. E. Roaf, St. Mary's Hospital, reader in physiology; Dr. Otto Rosenheim, King's College, reader in biochemistry; Mr. J. Henderson Smith, Lister Institute, reader in bacteriology; Dr. H. M. Turnbull, London Hospital, reader in morbid anatomy; and Dr. J. S. Edkins, Bedford College, reader in physiology. Dr. E. Barclay-Smith was appointed to the University professorship of anatomy at King's College, and Dr. E. P. Cathcart to the University professorship of physiology, tenable at the London Hospital Medical College. The report of the professor of protozoology (Professor E. A. Minchin) for the year ended June 30th, 1914, was received and forwarded to the Colonial Office. A grant of £50 was made out of the Dixon fund to Mr. J. A. Gardner, University of London Physiological Laboratory, for researches into lipid substances. The following additions were made to the Faculty of Medicine: Mr. R. C. Acland, Professor E.

Barclay-Smith, Professor E. P. Cathcart, Mr. R. W. Collum, Mr. T. J. Evans, Mr. R. A. Greeves, Dr. P. Haas, Dr. R. C. Jewesbury, Dr. E. Macnamara, and Mr. C. A. Pannett. It was announced that the Chancellor had reappointed Sir James Barr, M.D., to be his representative upon the Court of Governors of the University of Liverpool. University medals in connexion with the M.D. examination have been awarded to J. N. Mehta (medicine) and J. C. Woods (mental diseases), of the London Hospital.

Dr. Andrew Hunter, a graduate of Edinburgh University, has been recently appointed to the chair of pathological chemistry in the University of Toronto, to succeed Professor J. B. Leathes, who resigned some months ago to accept an appointment in the University of Sheffield. Dr. Hunter was associated with Professor E. A. Schaefer for three years, then went to Cornell University, Ithaca, New York, as associate professor of biochemistry. Subsequently he was appointed biochemist in the United States Public Health Service at Washington, D.C., whence he came to Toronto.

Dr. A. Wood Smith, late physician to the Glasgow Royal Infirmary, has been appointed honorary consulting physician to that institution.

MEDICAL MAGISTRATE.—Dr. Richard Emmett has been placed on the Commission of the Peace for the county borough of Portsmouth.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Naval Medical Compassionate Fund Bill.

A BILL "to make further and better provision with regard to the Naval Medical Compassionate Fund" has been introduced into the House of Commons by Mr. G. LAMBERT, Civil Lord of the Admiralty. It was read a first time.

The text of the Bill has been printed. It is in the following terms:—

Whereas under an Order in Council dated the thirteenth day of August eighteen hundred and seventeen the Naval Medical Supplemental Fund Society was established for the relief of widows of medical officers in the Royal Navy: And whereas it was provided in that Order that if any bequest or donations should be made in favour of the society, the principal amount thereof should be reserved separately as a compassionate fund, and that the interest should be distributed, at the discretion of the President and Court of Directors of the society, among the orphans of deceased members thereof, and that each member of the society, on his promotion or on his appointment to any permanent civil situation, should contribute to the compassionate fund a fee equal to one week's pay: And whereas in pursuance of the Naval Medical Supplemental Fund Society Winding-Up Act, 1861, the society has been wound up, but that Act provided that notwithstanding the winding-up of the society the above-mentioned compassionate fund should continue, but on a voluntary instead of a compulsory basis, and enacted that the interest thereof should be distributed among the orphans of those members of the society who had died and the orphans of those naval medical officers who had theretofore contributed or who should thereafter voluntarily contribute any such fee as aforesaid to the compassionate fund, but that no person should thereafter be compelled or liable to pay a fee to the compassionate fund: And whereas the said Act made no provision for the future management of the said fund, but the said fund has in fact remained under the management of a body consisting of the Secretary to the Admiralty, the Medical Director-General of the Navy, and certain medical naval officers who have contributed to the fund, and now consists of the sum of ten thousand six hundred pounds two and a half per centum consolidated stock: And whereas it is expedient to make provision for the management of the said fund and to alter the terms of contribution thereto and the nature of the benefits therefrom in manner hereinafter appearing:

Be it therefore enacted by the King's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. (1) His Majesty may by Order in Council provide—
(a) for constituting new trustees of the said fund and for vesting the fund in such trustees; (b) for filling vacancies

in the office of trustee and for vesting the fund in the trustees for the time being without conveyance or assignment; (c) for vesting the management of the fund, the determination of the persons to receive benefits therefrom, and the distribution thereof amongst such persons, in such body as may be determined by the Order, being a body representative of the naval medical service, either with or without the addition of representatives of the Admiralty; (d) for enabling all persons who are or who may hereafter become naval medical officers, or who may at any time have been naval medical officers, to become subscribers to the fund; (e) for determining the terms of subscription and the manner and time of payment thereof; (f) for making eligible to benefits from the fund the widows and orphans of all persons who at the time of the making of the Order may have contributed to the fund, and, subject to such conditions as may be prescribed by the Order, of persons who may after that date have become subscribers to the fund; and the Order may contain any incidental, consequential, or supplemental provisions which may appear to be necessary or proper for the purposes of the Order. (2) An Order in Council under this Act may be altered or revoked by a subsequent Order in Council.

2. This Act may be cited as the Naval Medical Compensate Fund Act, 1915.

A schedule to the Bill provides for the repeal of certain provisions in existing enactments.

Report of the Central Midwives Board.

The report on the work of the Central Midwives Board for the year ended March 31st, 1914, has been issued. It is therein stated that the Midwives Roll on March 31st, 1914, contained the names of 37,290 women, an increase for the year of 1727. This latter figure shows a reduction of 211 in the numbers added to the roll during the year, as compared with the previous year. Of the total, 16,989 have passed the Board's examination and 9583 have been admitted to the roll in virtue of prior certification under Section 2 of the Midwives Act. The total number of trained midwives amounts to 26,572 and of untrained to 10,718, the percentages being 71.3 and 28.7 respectively. At the same period last year the percentages were 69 and 31 respectively. The proportion of trained midwives increases steadily as the names of the untrained women disappear from the roll, but it must be remembered that a large number of the former, which may be estimated at not less than 60 per cent., do not practise as midwives in England or Wales. As far as can now be estimated the proportions of trained and untrained women in actual practice are about equal. Last year, of those practising as midwives, the untrained exceeded the trained.

HOUSE OF COMMONS

WEDNESDAY, FEB. 10TH.

Vaccination and Small-pox.

Mr. YEO asked the President of the Local Government Board whether he was aware that more than half the children born in England and Wales were now escaping vaccination and that small-pox had been almost entirely absent since the passing of the Vaccination Act, 1907; and, if so, whether he would consider the desirability of arranging that vaccination should now be entirely voluntary.—Mr. HERBERT SAMUEL replied: The statements in the first part of the question are substantially correct, except that there was no marked change in the number of deaths from small-pox following upon the passing of the Vaccination Act, 1907. It is not the intention of the Government to introduce legislation on the subject.

St. John Ambulance Brigade.

Replying to Mr. THOMAS, Mr. H. BAKER (Financial Secretary to the War Office) said: All men of the St. John Ambulance Brigade who are employed in military hospitals are enlisted for the Royal Army Medical Corps and are treated for pay and allowances, including separation allowance, in all respects as regular soldiers.

Drug Accounts Regulations in Scotland.

Mr. PRINGLE asked the Prime Minister whether his attention had been called to an interdict granted by Lord Anderson in the Court of Session on Feb. 2nd on the application of the Glasgow Insurance Committee ordaining the Scottish Insurance Commissioners to cancel any directions given by them for laying the National Health Insurance (Drug Accounts Committee) Regulations (Scotland), 1914, before both or either of the Houses of Parliament; whether the application was made and granted on the ground that no petition against the Order was possible in this House because the Government was to occupy the whole time of the House; whether under the Order of Feb. 3rd the opportunity to petition against Orders and Regulations laid upon the table of the House had been taken away; and, if so, whether the Government would propose an amendment of the Order of Feb. 3rd whereby the right to petition against Orders and Regulations laid upon the table would be restored.—Mr. ASQUITH furnished the following written reply: My

attention has been called to the matter referred to. It must not be taken to accept the statements made in the second branch of the question, but the grounds on which the application was made are, I believe, accessible to my honourable friend. As under the Order of Feb. 3rd, no opportunity would arise of discussing petitions against such Orders and Regulations, the Government will endeavour to make some arrangement that time should be given when discussion is necessary and desirable.

Health of the Army.

Speaking in the course of the debate on army estimates, Mr. TENNANT (Under Secretary for War) made reference to the service rendered to the country, and particularly to the War Office and the Royal Army Medical Corps, by the British Red Cross Society, the St. John Ambulance Association, and voluntary agencies generally all over the country.

He should like to endorse the eulogy which had been passed on them by the noble lord the Member for Hitchin (Lord Robert Cecil). He (Mr. Tennant) had tendered his acknowledgment of the admirable manner in which they had helped in every possible way. It was a pleasing fact that the St. John Ambulance Association and the British Red Cross Society, which were previously acting in rivalry the one with the other, were now working under a joint committee, which tended, of course, to more efficient work being achieved by both. The question had been raised of the evacuation of hospitals at Boulogne and elsewhere, and it had been suggested that the wounded had been moved too early from these hospitals in order to make room for others. That was a real difficulty. The War Office authorities were anxious that the sick and wounded should be left in the base hospitals as long as possible, and so much so was that the case that if he mentioned the fact that recently only 700 odd beds were vacant at Boulogne, he thought that it would be accepted as proof of the excessive care taken to keep the sick and wounded in the base hospitals and to prevent their removal too early. (The remarks of the right honourable gentleman on the subject of the inoculation of the troops against typhoid were summarised in last week's issue of THE LANCET.)

Mr. W. LONG expressed regret at the delay of the Government in coming to a decision on the question of making inoculation compulsory in the army. For future recruits inoculation ought to be made compulsory.

THURSDAY, FEB. 11TH.

Recoveries of Wounded Soldiers.

Sir GEORGE SCOTT ROBERTSON asked the Prime Minister how many out of the 104,000 casualties in the Expeditionary Force had now returned to duty.—Mr. ASQUITH replied: I fear that it would be contrary to the public interest to give exact figures, but my honourable friend and the House will be glad to know that about 60 per cent. of the wounded recover and become fit for service.

Treatment of Nerve Strain amongst Soldiers

Mr. DUNCAN MILLAR asked the Under Secretary for War whether the Red Cross military hospital which had been opened in Lancashire for the reception of uncertifiable soldiers suffering from nerve strain was solely under War Office control, or whether it was visited by Lunacy Commissioners and under lunacy administration.—Mr. TENNANT answered: The hospital referred to is an exclusively military hospital, and the reception, care, and discharge of the soldiers admitted are under the sole control of the War Office. The soldiers are not certified and are not under lunacy jurisdiction. The premises, however, are the property of the Board of Control, and some members of the Board visit the institution from time to time in order to supervise such matters as supplies, heating, repairs, and the maintenance of the premises, but they in no way concern themselves with the treatment of the patients.

Non-inoculated Soldiers.

Mr. TICKLER asked the Under Secretary for War whether he was aware that men who had joined Kitchener's Army, now in training at Brocklesby, had been informed that unless they consented to be inoculated against typhoid they would not be allowed to proceed to the front with their companions; and whether this was in accordance with the instructions of the War Office.—Mr. TENNANT answered: No such circumstances as the honourable gentleman describes have been reported. I stated in an answer to the Member for Haggerston on Nov. 23rd the position of inoculated men as regards the probability of their proceeding to the front. The matter remains as it then stood.

The Rum Ration.

Mr. CURRIE asked the Under Secretary for War whether rum was issued as a ration to troops at the front; if so, under what conditions it was issued; whether young men were forced in any circumstances to take rum as a ration; whether he was aware that there was a popular belief to this effect; and, if so, whether he would cause public contradiction of the belief to be made in view of its prejudicial effect upon recruiting.—Mr. TENNANT said in reply: I would

refer the honourable Member to the full answer which I gave on Nov. 16th. I think the true state of the case should be sufficiently clear, but I may repeat that men are not forced to take rum as a ration.

Mr. CURRIE: Would the right honourable gentleman be good enough to communicate a copy of his answer to Sir Thomas Barlow, the President of the Royal College of Physicians, who, if correctly reported in the *Times* of the 9th inst., entertains an extraordinary conception?—Mr. TENNANT: Yes, Sir, I shall be very glad to do so.

Prevention of Dope Poisoning in Aircraft Factories.

Mr. ROWLANDS asked the Under Secretary of State for the Home Department whether he received a report of the inquest held at Crayford on Jan. 8th in connexion with the death from dope poisoning of a young woman employed in varnishing the wings of aeroplanes; whether any similar cases had occurred; and whether measures had been successfully taken to ensure the safety of the workers using dope.—Mr. CECIL HARMSWORTH answered: Several cases of this poisoning occurred at one or two aircraft factories towards the end of last year, and at the Home Secretary's request a full investigation was made by Dr. Willcox, senior analyst to the Home Office, and Dr. Legge, medical inspector of factories. Their inquiries showed that the poisoning was caused by the fumes given off by the varnish, and could be prevented by the installation of a suitable system of ventilation which would effectually carry off the fumes. Steps were immediately taken in concert with the Admiralty and the War Office to secure the provision of effective means of ventilation in every aircraft factory where the dope is being used, and there is every reason to believe that these measures will be successful. No further case of poisoning has been reported since the one referred to by my honourable friend.

Mr. ROWLANDS: Are the authorities thoroughly well satisfied that the precautions taken will secure the safety of the lives of those engaged in this occupation of varnishing, and will there be an official report of the examination and inquiry?—Mr. CECIL HARMSWORTH: I understand that the authorities are thoroughly satisfied with the precautions now being taken.

Medical Inspection of School Children.

Sir W. BYLES asked the President of the Board of Education whether, in accordance with Section 13 of the Education (Administrative Provisions) Act, 1907, and Section 3 of the Employment of Children Act, 1903, he would at once direct all rural education authorities to provide for the medical inspection of all children leaving school for agricultural employment and direct them to prepare and serve on the employer of each child such certificate as was contemplated by the Acts cited and justified by the condition of health and education of the child; and whether he would order that the full details of each case should be immediately reported to the Board of Education and publish them in a Parliamentary paper weekly during the continuance of the war.—Mr. J. A. PEASE said in reply: Provision is already made in the code for the medical inspection of all children after reaching the age of 12, and no facts have been brought to my notice which would justify the imposition upon all local education authorities of such an addition to the work of school medical service as my honourable friend suggests. Any inquiry as to the Employment of Children Act, 1903, should be addressed to the Home Secretary.

Mr. W. THORNE: What happens when children leave the school below the age of 11? Is there any medical inspection then?—Mr. PEASE: Not if they leave at 11, but under the Robson Act there should only be a partial exemption at 11. There ought to be two medical inspections before the age of 11. If they leave at 11 they may escape the third or final medical inspection, which takes place at the age of 12.

Cases of Diphtheria.

Mr. FELL asked the President of the Local Government Board whether his attention had been called to the numerous cases of diphtheria which were occurring in various parts of the country; whether he was making inquiry into the causes of this outbreak; and whether he proposed to issue any instructions dealing with the matter.—Mr. HERBERT SAMUEL replied: Although in the last quarter of 1914 the number of cases of diphtheria was somewhat in excess of that for 1913, I am glad to state that the number of cases notified in England and Wales during the first five weeks of this year is about 1000 less than the number notified in the corresponding period last year. Returns of notified cases are received weekly from each district. These are examined, and it is a matter of routine practice in my department to call for special reports on outbreaks, and if necessary to direct a medical inspector to make a local investigation.

Mr. FELL: Is it not the case that there have been numerous outbreaks in some places, and have not a good many deaths occurred during the past few weeks?—Mr. H. SAMUEL: I am informed that the cases of diphtheria are distributed over a

very large number of areas, and that there have been few considerable outbreaks in any particular localities.

Royal Commission on Sewage Disposal.

Replying to Sir J. YOXALL, Mr. H. SAMUEL said: The final report of the Royal Commission on Sewage Disposal has now been signed and will be issued shortly.

MONDAY, FEB. 15TH.

Diseases amongst the Troops.

In reply to Mr. ROWLANDS and Mr. W. THORNE, who asked for particulars as to the cases and deaths among the Expeditionary Force from disease since the outbreak of war, Mr. TENNANT said that he would furnish them with a return on the subject. It is as follows:—

Return showing the Number of Cases and Deaths amongst the Expeditionary Force and the British Troops in the United Kingdom owing to Certain Diseases, from August 1st, 1914.

		Typhus fever.	Typhoid fever.	Cholera.	Small-pox.	Scarlet fever.	Diphtheria.	Measles.	Dysentery.	Pneumonia.	Cerebro-spina meningitis.
Expeditionary Force. ¹	Cases	0	625 ⁴	0	=	196	*	175 ³	*	*	*
	Deaths	0	49 ⁴	0	=	4	=	2 ³	=	*	*
British troops in the United Kingdom. ²	Cases	0	262	0	1	1379	783	1045	215	1508	62
	Deaths	0	47	0	0	22	6	65	1	301	26

¹ The figures in this class include cases and deaths up to Feb. 11th, 1915.

² The figures in this class include cases and deaths up to Jan. 31st, 1915.

³ These figures include Indian troops—cases 5, deaths 0.

⁴ These figures include Indian troops—cases 25, deaths 4.

* Returns for these diseases are not at present available.

There have been no cases of cholera or of typhus either in the Expeditionary Force or amongst the British troops in the United Kingdom.

Inoculation in the Army.

Replying to Mr. PETO, Mr. TENNANT said that he was not in a position to announce any change of policy with reference to the inoculation against typhoid fever of officers and men in the army, but he would like to inform the House that 97 per cent. of the 29th Division had been inoculated.

The Enlistment of Medical Students.

Mr. MCCALLUM SCOTT asked the Under Secretary of State for War whether he was aware that the calling out of numbers of medical students in the Territorial Force and their enlistment in other forces were likely to result in a shortage of doctors at an early date, to the injury both of the nation and of the army; whether since this fact became known many medical students had been willing to return from the army to the universities in order to qualify as medical practitioners at the earliest possible date; and whether the Secretary of State was prepared to permit such persons to resume their medical course.—Mr. TENNANT replied: Arrangements have been made for the return to their professional studies of medical students serving in medical units of the Territorial Force. Students in their final year of study who have only their final examinations to pass may also be released from the combatant corps if they apply.

TUESDAY, FEB. 16TH.

Medical Officers of the Territorial Force.

Mr. ROBINSON asked the Under Secretary of State for War whether, in view of the fact that medical men fresh from the schools received 24s.—more than a major's pay—whilst medical officers who had for years been training with the Territorial Force and had in many cases left large practices received only the pay of their rank and neither the allowances granted in the field, the £60 gratuity at termination of the war, nor prospect of pension, he would cause inquiry to be made with a view to more equitable treatment being given to the more experienced officers.—Mr. TENNANT answered: As I have already explained, it may be found necessary to give special rates to officers commissioned on emergency, but there is no intention of making this universal. I should add that a major of the Royal Army Medical Corps receives 28s. a day in pay and field allowance, while the medical officer specially commissioned receives 24s. inclusive of all cash allowances.

WEDNESDAY, FEB. 17TH.

Frost-bite amongst the Troops.

Mr. SANDERSON asked the Under Secretary of State for War whether he could state the number of cases of frost-bite among the troops of the Expeditionary Force; whether any, and if so how many, waterproof stockings or trench-waders

had been furnished to such troops; and whether any oilskin coats to wear with the same had been supplied in place of the usual army greatcoats.—Mr. TENNANT said in reply: The total casualties from frost-bite to Jan. 24th last amount to 9175. Large numbers of gum boots and similar articles and waterproof coats and capes have been provided in addition to the usual army boots and greatcoats.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

AUSTIN, E. C., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Medical Superintendent of the Withington Poor-law Institution.
DANIELS, DAVIS, M.D., B.S. Lond., F.R.C.S. Eng., has been appointed a Senior Surgeon to the Mansfield General Hospital.
JOHNSON, J. STAFFORD, M.B., B.Ch. N.U.I., has been appointed Temporary Resident Surgical Registrar at the Richmond, Whitworth, and Hardwicke Hospitals.
MCFARLAN, W. H., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Hawes District of the county of Yorks, North Riding.
NEALE, T. NORMAN, L.A.H. Dub., has been appointed Dispensary Medical Officer for the Powerscourt District, Dublin.
PICK, LAWRENCE, M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Schools Medical Officer to the Barry Education Committee.
POLLOCK, J. H., M.B., B.Ch. N.U.I., has been appointed Temporary Resident Pathologist at the Richmond, Whitworth, and Hardwicke Hospitals.
SALTER, C. E., M.D. Lond., F.R.C.S. Eng., has been appointed Temporary Assistant Medical Officer of Health and Assistant School Medical Officer for Scarborough.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ASHTON-UNDER-LYNE DISTRICT INFIRMARY AND CHILDREN'S HOSPITAL.—Senior House Surgeon. Salary £140 per annum, with board, residence, washing, &c.
BARROW-IN-FURNESS, NORTH LONSDALE HOSPITAL.—House Surgeon. Salary £150 per annum, with residence, board, and laundry.
BEXLEY, KENT, LONDON COUNTY ASYLUM.—Locum Tenens Medical Officer. Salary 6 guineas a week, with quarters, board, and washing.
BIRKENHEAD AND WIRRAL CHILDREN'S HOSPITAL, Woodchurch-road.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.
BIRKENHEAD BOROUGH HOSPITAL.—Senior House Surgeon. Salary £120 per annum, with board and laundry. Also Junior House Surgeon. Salary £100 per annum, with board and laundry.
BIRMINGHAM CITY MENTAL HOSPITAL, Rubery-hill.—Female Junior Assistant Medical Officer. Salary £200 per annum, with apartments, board, laundry, &c.
BIRMINGHAM GENERAL DISPENSARY.—Resident Medical Officer, unmarried. Salary £240 per annum, with apartments, fire, lights, and attendance.
BIRMINGHAM, YARDLEY-ROAD SANATORIUM AND ANTI-TUBERCULOSIS CENTRE.—Third Assistant Medical Officer. Salary £200 per annum, with board and residence.
BLACKBURN AND EAST LANCASHIRE ROYAL INFIRMARY.—House Surgeons, Senior and Junior. Salaries £150 and £130 per annum, with board, residence, and laundry.
BOOTLE COUNTY BOROUGH.—Temporary Clinical Tuberculosis Officer. Salary at rate of £400 per annum.
BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £120 per annum, with board, residence, and laundry.
BRIDGWATER HOSPITAL.—House Surgeon, unmarried. Salary at rate of £125 per annum, with board, lodging, and washing.
BRISTOL EYE HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.
BRISTOL GENERAL HOSPITAL.—Resident Obstetric Officer for six months. Salary at rate of £120 per annum, with board, residence, &c.
BRISTOL ROYAL INFIRMARY.—Throat, Nose, and Ear House Surgeon. Salary at rate of £120 per annum, with board, apartments, and laundry.
BROADMOOR STATE CRIMINAL LUNATIC ASYLUM, Crowthorne, Berks.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, rooms, washing, and attendance.
BURNLEY, VICTORIA HOSPITAL.—House Surgeon. Salary £135 per annum, with residence, board, and washing.
BURSLEM, HAYWOOD HOSPITAL.—Female Resident Medical Officer. Salary £100 per annum, with board, residence, and laundry.
BURY INFIRMARY.—Junior House Surgeon. Salary £150 per annum, with board, residence, and washing.
CANCER HOSPITAL, Fulham-road, S.W.—House Surgeon for six months. Salary £100 per annum.
CANTERBURY, KENT COUNTY ASYLUM, Chatham.—Third Junior Assistant Medical Officer. Salary £250 per annum, with quarters, board, washing, &c.
CARMARTHEN, JOINT COUNTIES ASYLUM.—Temporary Second Assistant Medical Officer. Salary at rate of £200 per annum, with board, lodging, washing, &c.
CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd-street, W.C.—House Surgeon. Salary at rate of £50 per annum, with board and residence.

CHESTER, CITY AND COUNTY OF THE CITY OF.—Assistant Medical Officer of Health. Salary £300 per annum.
CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £75 per annum, with board, residence, and washing. Also Resident Medical Officer. Salary £200 per annum, with board, &c.
CLAYBURY, LONDON COUNTY ASYLUM, Woodford Bridge, Essex.—Fifth Assistant Medical Officer, unmarried. Salary £200 per annum, with board, apartments, and washing.
DARLINGTON HOSPITAL AND DISPENSARY.—House Surgeon. Salary £150 per annum, with board, attendance, and laundry.
DEVONPORT ROYAL ALBERT HOSPITAL.—House Surgeon, unmarried. Salary £150 per annum, with board and laundry.
DEWSBURY AND DISTRICT GENERAL INFIRMARY.—House Surgeon. Salary £170 per annum, with board, residence, and laundry.
DUBLIN, SCHOOL OF PHYSIC, TRINITY COLLEGE.—Mary Louisa Prentice Montgomery Lectureship in Ophthalmology. Salary about £160 per annum.
DUDLEY, GUEST HOSPITAL.—Senior Resident Medical Officer. Also Assistant House Surgeon for six months. Salary £150 and £120 per annum respectively, with board, residence, attendance, and washing.
DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—Female Resident House Surgeon. Salary £120 per annum.
EAST HAM, COUNTY BOROUGH OF.—Tuberculosis Officer. Salary at rate of £500 per annum.
ECCLES AND PATRICROFT HOSPITAL.—House Surgeon, unmarried. Salary £70 per annum, with board, lodging, and washing.
EXETER, ROYAL DEVON AND EXETER HOSPITAL.—Senior House Surgeon for 12 months. Also House Physician and Assistant House Surgeon for six months. Salary at rate of £250 per annum for senior post and £150 for junior posts, with board, apartments, and washing.
FIJI (THE GILBERT AND ELLICE ISLANDS PROTECTORATE AND THE SOLOMON ISLANDS PROTECTORATE).—Three Medical Officers. Salary £350 per annum, free quarters provided.
GLAMORGAN COUNTY COUNCIL.—Medical Officer for Inspection of Children in Public Elementary Schools. Salary at rate of £300 per annum.
GLASGOW ROYAL MATERNITY AND WOMEN'S HOSPITAL.—Two Indoor House Surgeons and Two Outdoor House Surgeons at the Hospital, and One Outdoor House Surgeon at the West End Branch (which is open only to Lady Graduates); indoor appointments for six months, and outdoor for three months.
GREAT YARMOUTH HOSPITAL.—House Surgeon, unmarried. Salary £200 per annum, with board, lodging, and washing.
HALIFAX ROYAL INFIRMARY.—Second and Third House Surgeons, unmarried. Salary £120 and £100 per annum respectively, with residence, board, and washing.
HOLBORN UNION INFIRMARY, Archway-road, N.—Second Assistant Medical Officer. Salary £150 per annum, with board, apartments, and washing.
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas.
HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Assistant Casualty Medical Officer, unmarried, for six months. Salary £30, with board, residence, &c.
HULL, CITY AND COUNTY OF KINGSTON-UPON-HULL.—Temporary Senior Tuberculosis Medical Officer. Salary at rate of £500 per annum.
HULL, VICTORIA CHILDREN'S HOSPITAL, Park-street.—Resident House Surgeon and Resident Assistant House Surgeon. Salary £60 and £50 per annum respectively, with board and laundry.
INVERNESS, NORTHERN INFIRMARY.—House Surgeon. Salary £100 per annum, with board, &c.
LABORATORIES OF PATHOLOGY AND PUBLIC HEALTH.—Bacteriologist. Salary £170 per annum.
LEICESTER ROYAL INFIRMARY.—House Physician. Salary at rate of £120 per annum.
LINDSEY (LINCOLNSHIRE) COUNTY COUNCIL.—Combined Temporary Assistant Tuberculosis and Assistant School Medical Officers. Salary at rate of £300 per annum.
LIVERPOOL CITY HOSPITAL, Grafton-street.—Visiting Physician. Salary at rate of £130 per annum.
LIVERPOOL, CITY OF.—Locum Tenens School Medical Officer. Salary 6 guineas per week.
LIVERPOOL COUNTY ASYLUM, Rainhill, near Liverpool.—Temporary Assistant Medical Officer. Salary £6 6s. per week, with apartments, board, attendance, and washing.
LONDON COUNTY COUNCIL LEWISHAM CENTRE FOR THE DENTAL TREATMENT OF SCHOOL CHILDREN, 46, Rushey-green, S.E.—Anæsthetist one half-day every fortnight. Salary £25 per annum.
LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Three House Surgeons and Two House Physicians, each for six months. Salary at rate of £60 per annum, with board and residence.
LONDON HOSPITAL, E.—Assistant Surgeon.
MANCHESTER, COUNTY ASYLUM, Prestwich.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, attendance, and washing.
MANCHESTER, ST. MARY'S HOSPITALS FOR WOMEN AND CHILDREN.—Resident Surgical Officer. Salary £90 per annum, with board and residence. Also House Surgeon for three or six months. Salary at rate of £70 per annum, with board and residence. Also House Surgeon at Whitworth-street West Hospital for three or six months. Salary at rate of £70 per annum, with board and residence.
METROPOLITAN BOROUGH OF HACKNEY AND STOKE NEWINGTON.—Tuberculosis Officer. Salary at rate of £500 per annum.
MIDDLESEX COUNTY ASYLUM, Napsbury, near St. Albans.—Temporary Assistant Medical Officer. Salary 6 guineas per week, with board, lodging, washing, and attendance.
MIDDLESEX EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary at rate of £300 per annum.
MILE END OLD TOWN INFIRMARY.—Senior Assistant Medical Officer and Junior Assistant Medical Officer. Salary £200 and £150 per annum respectively, with board, lodging, and washing.
MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Junior House Surgeon for six months. Salary £85 per annum, with board, residence, and laundry.
NEWPORT (MON.), ROYAL GWENT HOSPITAL.—Resident Medical Officer. Salary for first six months at rate of £100 per annum, second six months £125, and third six months £150, with board, residence, and laundry.

Births, Marriages, and Deaths.

BIRTHS.

FORSTER.—On Feb. 11th, at Woodhill, Crowthorne, Berks, the wife of Lieutenant C. M. Forster, R.A.M.C., of a daughter.
 SMYTH.—On Feb. 13th, at Southcroft, Manor-road, High Barnet, the wife of Francis Radway Smyth, M.R.C.S., L.R.C.P., of a daughter.
 WYARD.—On Feb. 13th, 1915, at 6, Connaught Mansions, Battersea Park, S.W., to Constance Enid, wife of Lieutenant Stanley Wyard, M.D., M.R.C.P., a daughter.

MARRIAGES.

GUNN.—MACDONALD.—On Feb. 6th, at the Catholic Apostolic Church, Edinburgh, James Turner Gunn, M.B., Ch.B., F.R.C.S. Edin., to Adelaide Lucy Frances, only daughter of Mr. and Mrs. N. D. Macdonald, Coll-Earn, Auchterarder.
 SKRIMSHIRE.—LOGAN.—On Jan. 16th, at St. Paul's Church, Poona, Francis Robert Bradley Skrimshire, Captain R.A.M.C., to Nona Jean, youngest daughter of the late C. B. Logan and of Mrs. Logan, Westmarch, Torquay.

DEATHS.

HUNTER.—On Feb. 4th, at 31, St. James-street, Paisley, N.B., John Baird Hunter, M.D. Glasg., of 3, Smithhills-street, Paisley, aged 73 years.
 MCGOWAN.—On Jan. 29th, 1915, at his residence, "Hill-side," Tabankulu, Pondoland, Cape Colony, of pneumonia, W. Oscar S. McGowan, M.B., Ch.B., eldest son of Dr. William McGowan, Maghera, Co. Derry. (Cablegram).
 MCKILLIAM.—On Feb. 7th, at his residence, Ballandalloch, Blackbeath, Robert McKilliam, M.D.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

VERMIN IN THE TRENCHES.

To the Editor of THE LANCET.

SIR,—The screeching of the shells and the ping of the rifles must be very trying to the nerves of our soldiers in the trenches, but the added filth and mud in these dwelling-places, with the forced personal uncleanness, is a physical strain of equal sacrifice to the men; and in the midst of this abnormal state of affairs the additional irritation of the wandering louse calls forth our aid for its immediate capture. Not that this can be done readily as in ordinary civil life, still there should be no difficulty in trapping these pests swarming in their ideal quarters. If trench existence is contrary to personal cleanliness and parasitical life is engendered, there is only one remedy, and that is poison. Both large and small vermin can be only successfully destroyed in this way when they are in abundance. Therefore some easily accessible weapon of destruction should be in the possession of every soldier, and in the emergency castor-oil, on the one hand, for application to sore places, while for poisonous duties a pepper-box containing pyrethrum powder, Keating's powder, or, best of all, flowers of sulphur. Now, the latter can be dusted into the clothing, the stockings, or in any part of the underclothing. When the body gets warm the effect of the sulphurous fumes on the parasites and the ova will soon tell. Then, when an opportunity occurs, a gipsy fire is suitably extemporised, and the clothes overhanging the products of combustion—i.e., smoke—will determine the life of the vermin. I am sure this simple suggestion will comfort the external body of our noble men at the front, and they will appreciate this remedy out of fashion. May I add that sulphite of soda, 2 drachms to 1 pint of water, for bathing the body is inimical to parasitic life.

I am, Sir, yours faithfully,
Alton, Hants, Feb. 9th, 1915. JOHN FREDK. BRISCOE.

To the Editor of THE LANCET.

SIR,—We notice in your valued publication of Feb. 6th that in an article dealing with this matter Lieutenant-Colonel S. Monckton Copeman quotes some directions for using:—

Water	...	...	...	10 gallons.
Jeyes' fluid	...	...	...	1½ ounces.
Soft soap	...	...	...	1½ pounds.

and the lather of this compound is to be allowed to dry on the garment. In the first place, soft soap is hygroscopic and therefore unsuitable to be mixed with something that is to be allowed to dry, and in the second place, there are many more effective vermin destroyers than this particular fluid.

It seems to us that a soap like our "Cofectant" soap or our biniodide of mercury soap, being soda soaps, allowed to dry on the garment would be a much greater protection than such a compound as suggested above, and not liable to cause the garments to keep damp. "Cofectant" has been proved to kill the eggs or larvae of vermin as well as the active units.

We are, Sir, yours faithfully,
EDWARD COOK AND CO., LIMITED,
(THOS. ALEX. COOK, Director.)
Feb. 16th, 1915.

"ANCIENT LIGHTS."

To the Editor of THE LANCET.

SIR,—An interesting survival of mediæval organotherapeutics in rural England came to my notice to-day. Measles of a rather severe type is epidemic here just now, and one of my patients, a sturdy boy aged 4, who had passed through a stage of heavy rash, has had a good deal of subsequent bronchial catarrh with troublesome night cough, but with no signs of pneumonia. This morning I found him distinctly better after a night of quiet sleep, and was just about to commend the action of the last bottle of medicine when the mother, who can neither read nor write, forestalled me. "I must tell you what we done," she said; and what they done was this. A wise old woman had seen the boy on the preceding evening. His cheeks were flushed, and she pointed out that this showed that the "inflammation" had set in, and advised them to get from the butcher the lungs of a sheep just killed, to make a deep cut in each lung, and to apply them each to one of the soles of the patient's feet, keeping them attached all night by a bandage. This was religiously done, and when taken off this morning the lungs were hotter than when applied, and had "drawn out all the inflammation." The credit for the boy's recovery will, I fear, not be mine. This piece of medical lore must have been handed down by word of mouth through many generations of illiterate people.

I am, Sir, yours faithfully,
Bromsgrove, Feb. 13th, 1915. H. CAMERON KIDD.

URINE IN CHILDREN'S DISEASES.

D. G. W.—With the exception of brief articles in works on diseases of children, such as Dr. Dawson Williams's "Medical Diseases of Infancy and Childhood," most of the references to the urine in relation to children's diseases occur in text-books dealing with the general aspects of urinary analysis. There are, for example, incidental references to the urine of children in Brandeis's "L'Urine Normale et Pathologique"; Neubauer-Huppert's "Analyse des Harns," Vols. I. and II.; Abderhalden's "Handbuch der Biochemischen Arbeitsmethoden," Vol. V., Part 1; Blumenthal's "Handbuch der Speziellen Pathologie des Harns"; and Mitchell's "Modern Urinology." The first-named book deals perhaps more fully than the others with the urine of children, and it gives several useful tables showing the composition at various ages. We do not at the moment recall any articles in recent medical literature dealing specially with the examination and diagnostic value of analyses of the urine in children.

Mr. Stanley Burns (Montreal).—The details should be sent to the Imperial Cancer Research Fund, 8-11, Queen-square, London, W.C.

Enthusiast.—We are informed on the best authority that our correspondent's argument is based upon misconception.

Dr. T. D. Harries.—The criticism does not, we hope, apply to the present generation.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Papers:—Mr. J. F. Twort and Prof. L. Hill: The Effect of the Depth of Pulmonary Ventilation on the Oxygen in the Venous Blood of Man.—Dr. A. J. Ewart: On the Function of Chlorophyll (communicated by Prof. A. C. Seward).—Mr. E. Heron-Allen: Contributions to the Study of Bionomics and Reproductive Processes of the Foraminifera (communicated by Prof. W. A. Herdman).—Mr. A. Compton: The Influence of the Hydrogen Concentration upon the Optimum Temperature of a Ferment (communicated by Prof. W. Bulloch).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY.
SECTION OF ODONTOLOGY (Hon. Secretaries—F. Coleman, F. R. Smyth): at 8 P.M.

Short Communications:

Dr. Ackerley: (1) Some Primary Factors in the Causation of Gingivitis; (2) Disappearance of Adeno-Fibroma of Breast after adequate treatment of Oral Sepsis.

Paper:

Dr. H. Ewan Waller: The Influences of the Thyroid Gland upon Dental Caries.

SECTION OF MEDICINE.—Members of the Section of Medicine are specially invited to attend the meeting of the Section of Odontology. (See above.)

TUESDAY.

SECTION OF MEDICINE (Hon. Secretaries—John Fawcett, Charles R. Box): at 5.30 P.M.

Dr. Frederick Taylor: Case of Multiple Pulsating Tumours Secondary to Hypernephroma.

Dr. Parkes Weber: (1) Bilateral Hypernephroma with Secondary Thrombosis of the Inferior Cava and Uramia; (2) Latent Addison's Disease revealed by the occurrence of Pneumonia.

THURSDAY.

SECTION OF NEUROLOGY (Hon. Secretaries—T. Grainger Stewart, H. Campbell Thomson): at 8 P.M.

Clinical Meeting.

Demonstration of Cases.

FRIDAY.

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE (Hon. Secretaries—G. S. Buchanan, William Butler): at 8.30 P.M.

Special Discussion:

The Epidemiology of Cerebro-spinal Meningitis (opened by Sir William Osler).

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Adjourned X Ray Evening. Items of Interest in Connexion with the War will be demonstrated and exhibited by Dr. A. C. Jordan, Dr. H. Orton, Mr. G. Scott, Dr. S. Melville, Dr. R. Knox, and others.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

WEDNESDAY.—8 P.M., Mr. W. J. Ashley: The Economic Position of Germany.

HUNTERIAN SOCIETY, Barbers' Hall, Monkwell-street, E.C.

WEDNESDAY.—9 P.M., Dr. T. D. Lister: Demonstration of an Apparatus for Producing Artificial Pneumothorax. Paper:—Dr. G. T. Western: Vaccine Therapy, its Present Scope.

CHILD STUDY SOCIETY LONDON, Royal Sanitary Institute, 90, Buckingham Palace-road, S.W.

THURSDAY.—6 P.M., Discussion on the Care and Development of the Child—from Ante-natal Period to Five Years of Age, Ante-natal Period, Dr. Eric Pritchard; Infancy, Miss J. Halford; One to Five Years, Dr. D. Forsyth.

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.
THURSDAY.—8.30 P.M., Paper:—Dr. E. G. Little: Rodent Ulcer, its Nature and Some Methods of Treating it.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c. ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY, WEDNESDAY, AND FRIDAY.—5 P.M., Hunterian Lectures:—Prof. A. Keith: The Anatomy and Mechanism of the Alimentary Canal. (Illustrated by specimens from the Museum of the College and by the use of the epidiascope.) (Lectures I., II., and III.)

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 11 A.M., Mr. Souttar: Demonstration of Minor Operations. 12 noon, Lecture:—Mr. Souttar: Abdominal Diagnosis. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 12 noon, Lecture: Dr. G. Stewart: Neurological Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynaecological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. Bernstein: Applied Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 12 noon, Lecture:—Mr. Souttar: Surgical Anatomy of the Abdomen. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Gynaecological (Dr. J. B. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. Howell Evans); Nose, Throat, and Ear (Mr. H. D. Gillies). X Rays and Electrical Methods (Dr. Metcalfe). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Clinical Demonstration:—Dr. A. G. Auld: Selected Medical Cases.

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynaecological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson); X Rays and Electrical Methods (Dr. Metcalfe).

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Dr. K. Sibley: Seborrhoea and Psoriasis.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Some New Growths.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

TUESDAY.—3 P.M., Prof. C. S. Sherrington: Muscle in the Service of Nerve. (Lecture VI.)

MANCHESTER HOSPITALS POST-GRADUATE CLINICS.

THURSDAY.—ANCOATS HOSPITAL, Mill-street.—4.30 P.M., Dr. Bythell: Military Radiography.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE

AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1914 were given in THE LANCET of Dec. 26th, 1914.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1914 are now ready. Bound in cloth, gilt lettered, price 16s., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.			TO THE COLONIES AND ABROAD.		
One Year	...	£1 1 0	One Year	...	£1 5 0
Six Months	...	0 12 6	Six Months	...	0 14 0
Three Months	...	0 6 6	Three Months	...	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

The Hunterian Oration

ON THE

TREATMENT OF WOUNDS IN WAR.

Delivered before the Royal College of Surgeons of England on Feb. 15th, 1915,

By SIR W. WATSON CHEYNE, BART., C.B.,
F.R.S., LL.D. EDIN.,
PRESIDENT OF THE COLLEGE.
(With Illustrative Plate.)

GENTLEMEN,—It is now nearly 122 years since the death of John Hunter, and since that time 67 orations have been delivered in his memory, most of them dealing with his life and work. Although I have not read these orations it did not seem likely that there was much left for me to say, but after perusing his works I thought that there might still be something fresh in a consideration of his scheme of life and disease in the light of our present-day knowledge. When, however, this war began so many other more pressing interests arose that I began to doubt whether such an oration would really be of interest, and therefore I gladly fell in with the wishes of some of the more warlike of my colleagues, and shall devote the greater part of this hour to the consideration of a very important subject—viz., the treatment of wounds in war.

JOHN HUNTER: HIS WAR EXPERIENCE.

John Hunter was always trying to solve puzzles. He never met with a point which he could not understand but he tried to find out its meaning, and his museum is an indication of the multifarious things in which he was interested and of the many facts which he collected with regard to them. At the same time he had that great characteristic of true genius, a vivid imagination, and he was always weaving theories to explain his puzzles and modifying or adding to them as seemed necessary. In this way he built up his great scheme of disease, which is full of ingenuity and interest. It does not, it is true, occupy any important place in the teaching of the present day, but the reason for that is that he had so few really basal facts to theorise on.

Among the many puzzles that we have to deal with there is none more urgent or important, especially at the present time, than the treatment of wounds in war. It is a puzzle which has exercised the minds of medical men since the world began, and it is still unsolved. And yet the solution is urgent, both out of gratitude to those who risk their lives for their country and also for the sake of the country itself. To attempt with all our strength to solve this puzzle is a matter of common gratitude, for we owe it to those brave men who risk their lives for our safety and well-being to minimise that risk as much as possible; and it is also a matter of national importance, because the more soldiers we save, and the sooner those who are able can be returned to duty, the greater is our strength.

John Hunter himself had some experience of war, and wrote an article on gunshot wounds which is of great interest, especially as regards the influence of the velocity of the bullet on the nature of the wound. There is no definite record in his writings as regards his war service, but Major

Howell, of the Royal Army Medical Corps, has collected a few facts concerning it. According to him John Hunter accompanied a British expedition to Belleisle in 1761, in which, in the attempts to land a force on the island, there were some 500 wounded men on whom Hunter was enabled to make his observations. His war experience was somewhat increased in the following year, as he went to Portugal for a few months. His connexion with military surgery did not, however, cease at that time, for he remained intimately connected with the army for many years in that he drew his half-pay regularly. In 1786 he returned to the active list of the army. In 1790 he became head of the Medical Department jointly with a physician, Sir Clifton Waitringham. In 1793, some months before his death, he became sole head of the Medical Department of the Army, and according to Howell he was really the first medical director-general of the army. It is interesting in passing to note, as showing the tendency of his mind, that during his service at Belleisle he studied the coagulation of the blood, and when he came home from his army service he brought with him 200 specimens of beasts, lizards, and snakes, which formed the foundation of his museum. A good many of his views on inflammation and on the treatment of wounds were also formed at that time.

TREATMENT OF WOUNDS IN RECENT WARS.

The history of the treatment of wounds in war would form a very interesting topic, but I shall only say a few words with regard to the treatment in recent wars. During the past all sorts of methods of treatment of wounds, whether in peace or in war, have been employed, but very little real advance was made till the Listerian period, and therefore our present interest in these matters only concerns recent wars.

The first war in which any attempt at Listerism was made was the Franco-Prussian War in 1870-71, but Lister's views had not made any great progress at that time, and the methods employed were very feeble and inefficient. The wounds were sometimes washed out with carbolic lotion, and oily solutions of carbolic acid were also employed as dressings, as well as other antiseptics such as acetate of alumina and permanganate of potash. Open wound treatment was also used in some hospitals, but the results were bad. On the whole, there was no great improvement as regards sepsis on this occasion. The statistics of a number of surgeons in this war give a mortality of 50·5 per cent. for amputations, and of 48·6 per cent. for resections of joints.

In the Russo-Turkish War in 1877 some more definite attempts were made to carry out the Listerian methods; but only the work of one or two individual surgeons is of any use for our purpose. In this war all those surgeons who tried Listerism emphasise the difficulty of getting the wounded for treatment at a sufficiently early period, which was generally laid down as within 12 hours after the injury. I need only refer to the work of Reyher, a Russian surgeon who had visited Lister's wards in Edinburgh, and who attempted to carry out his methods as thoroughly as he could. He also emphasises the difficulty of getting the patients and of carrying out the treatment during the first 12 hours, and therefore he had only a comparatively small number of such patients, whom he terms 'primary antiseptic cases.' In his

statistics he stated that his mortality in cases of injuries of joints which came under observation within 12 hours and were treated conservatively was 13 per cent., while in those which were brought in later than 12 hours and in which no thorough disinfection could be made it was 61.5 per cent. As regards compound fractures coming under observation within 12 hours the mortality in primary antiseptic cases was 18.1 per cent., while in those which came under observation later it was 35.3 per cent. The mortality of all the cases treated primarily—that is to say, within 12 hours—including compound injuries of joints, compound fractures, primary resections of bones, and primary amputations, was 6.1 per cent., while that of similar cases which came under observation later than 12 hours was 32.1 per cent. Apart from the delay in getting the patients from the field, the disinfection of each case by the method he employed took some time, and therefore he always took the worst cases first. Reyher's method consisted, in cases of bad wounds of joints, in laying them open, thoroughly washing them out in every direction with 1:20 carbolic acid lotion, free drainage, and antiseptic dressings. In addition, some surgeons—for example, Fischer—recommended that if the wounds were badly soiled these parts should also be treated with strong chloride of zinc lotion.

The next war to which I need refer was the Chino-Japanese War (1894-95), and there also in the Naval Department, which is the only side I know, attempts were made to carry out Listerian treatment. The treatment consisted in washing out the wounds with 2½ to 3 per cent. carbolic lotion, disinfecting the skin, extracting such foreign bodies as were easily accessible, and the application either of antiseptic dressings such as sublimate gauze and carbolic gauze, or of absorbent cotton-wool. As in most cases the wounds could not be thoroughly disinfected in the time at their disposal the surgeons filled them up with iodoform. The result was that nearly all the wounds suppurated, and as an explanation it was pointed out that time did not permit of anything like a thorough disinfection of the wound, and that these wounds were irregularly torn, leaving irregular spaces in which organisms could lie and escape the action of the antiseptic, while the surrounding tissues had lost their resisting power and organisms could multiply readily in them. In this war the average time for the healing of a shell wound was 2½ months.

In the South African War, so far as I know, no thorough attempt was made to disinfect the wounds; indeed, in most cases no special treatment of the wounds was found to be necessary, owing to the fact that for the most part they were small. The majority of these wounds did well if they were allowed to scab over. There were comparatively few large wounds; those which did occur suppurated, and the ordinary troubles which are taking place now were also met with then. It is true, I do not remember to have seen a case of tetanus, but I saw several cases of acute spreading gangrene.

The last great war was the Russo-Japanese War, and by that time antiseptics had been more or less given up, and here we have an example of the so-called aseptic treatment combined with the imperfect use of antiseptics. The wounds were not handled nor washed out with antiseptics, but they were dusted over with a powder of salicylic

and boracic acids and dressed with sterilised gauze. The report of the result runs as follows:—

The wounded, when admitted to hospital, were found to have all their wounds inflamed in a somewhat advanced stage—the bruised tissues were already sloughing off and a reactionary inflammation was already developing around the lips of the wounds. The larger and still open wounds were in most instances covered with a dark grey slough and no signs of firm and red granulations were to be seen.

LESS VIRULENT SEPSIS OF WOUNDS.

If we review these wars we see that, with the single exception of Reyher, no real attempt at the disinfection of wounds has been carried out. Nor has sepsis been conquered; all large wounds suppurate and sometimes slough, and various septic troubles arise. It is true that such septic conditions as phagedæna, pyæmia, &c., with their terrible mortality, are not so frequent as they were before the Listerian era, but otherwise the results are very much the same. In my opinion the explanation of these improved results is as follows. The very bad results in former days were, I have no doubt, due not so much to infection of the wound at the time as to transference of infective material directly from one patient to another by the surgeon and attendants at the dressings. In former days, when the process of infection was not understood, case after case was dressed with the same instruments, which were often not cleaned at all or only rubbed with a cloth or rinsed in water; the surgeons did not even wash their hands after every case. Now we know that if the virulence of a pathogenic organism has diminished during culture the best way of restoring its virulence is by passing it through a series of animals, and further, the virulence of a virulent organism can often be much exalted in the same way. I believe that many of the tragedies in pre-Listerian times arose from the continued transference of increasingly virulent organisms from patient to patient by the surgeon or the attendants. One result of Lister's teaching is that, apart from strict aseptic work (and by that I mean work which ensures asepsis in a wound quite apart from whether antiseptics are used or not), everyone who has to deal with wounds takes care, or ought to take care, by disinfecting the instruments before being used for a fresh patient and avoiding infection of dressings, &c., not to carry organisms from one patient to another. My view is that the chief explanation of the less virulent sepsis which is present in these wounds to-day and to which surgeons point with considerable self-satisfaction, and indeed most that has as yet been gained from modern methods of wound treatment in the case of war, is the result of this simple cleanliness rather than of improved treatment of the wounds themselves.

Before I go any further let me make clear what I mean by sepsis. In speaking of sepsis and septic wounds I refer to the conditions (suppuration, cellulitis, septicæmia, pyæmia, osteomyelitis, and so on) brought about by the ordinary pyrogenic organisms. Whether the amount of disturbance caused is much or little, a wound in which these organisms are growing freely is a septic wound. In the present war, I fancy, attention is chiefly concentrated on the foul smell of the wounds and on the occurrence of tetanus and acute spreading gangrene rather than on the suppurative condition. Now, foul smell in a wound does not mean anything much worse than a septic wound without a foul smell. The odour is due to the presence of some organism (generally a

saprophyte) which produces foul-smelling gases, and though they may increase the amount of toxins absorbed they are easily got rid of by irrigation, free drainage, &c. Tetanus and acute spreading gangrene, again, are independent diseases which happen to get into the wound along with soil, and are to a certain extent independent of the question of sepsis, although they seldom occur in wounds which are not also septic. Further, these diseases, though very terrible, are comparatively rare.

As regards the present war, I do not suppose we can know accurately what the proportion of tetanus is until statistics are made up at the end of the war; but in a note issued to the medical staff in December it is stated that about 0.2 per cent. of the wounded had been attacked by tetanus among the troops in France, and that some further cases had developed after the arrival of the wounded in this country. In recent wars the number of cases of tetanus has averaged less than 1 per cent. of the wounded (varying from 1.2 to 0.26 per cent.). The proportion of acute spreading gangrene is somewhat greater, but we may take it that at most only some 3 per cent. of the wounded will probably be affected with these diseases. Tetanus and spreading gangrene are very terrible diseases, and hence, no doubt, the reason why undue prominence is being given to them; but what I am trying to work out is how best to deal with the other 97 per cent. of the wounded so as to avoid the much more common and often very serious sepsis. Incidentally I think it will be found that in concurrence with the disappearance of the septic diseases the proportion of cases of tetanus and acute spreading gangrene will also diminish.

CONSIDERATION OF METHODS OF TREATMENT.

Now in considering the prevention and treatment of septic infection of wounds it seems to me that there are theoretically three ways in which we may oppose the attacks of the parasitic invaders: 1. To strengthen the natural protective forces in the body to such an extent that they may be able to resist and destroy the invading organisms. 2. To destroy the organisms after they have broken through the natural defences of the body and have established themselves in the injured part or the body generally. 3. To prevent the growth of or to destroy the organisms at their point of entrance into the body before they have had time to establish themselves there.

The Strengthening of the Natural Defences.

The first point raises the very difficult question of immunity and the action of toxins introduced into the body by the surgeon—the so-called vaccines. These questions are much too abstruse for me to go into to-day, if indeed I were competent to do so, and besides they are very far from being worked out; indeed, the theories of this year may very probably not be the theories of two or three years hence. I may, however, say a few words as a clinician on the way in which the matter so far strikes me in reference to the question under consideration.

In former years the use of vaccines was advocated as a prophylactic measure, a certain amount of immunity being produced, or the existing amount of immunity being increased, by setting up a mild attack of the same or of a closely allied disease. This was the process of inoculation and later of vaccination against small-pox, the latter

being produced by setting up a mild attack of a similar disease (if not the same disease), viz., cow-pox, and the value of this measure is universally acknowledged except by a few cranks. The first to extend the process to bacteric diseases was Pasteur, who by the previous injection of organisms, weakened as regards their virulence, was able to induce a considerable amount of protection against the assaults of living and more virulent bacteria of the same kind. Thus he was able to vaccinate chickens against chicken cholera, and sheep and cattle against anthrax. At the present time antityphoid inoculations are being very largely employed and, in the opinion of those best qualified to judge, with great advantage. Prophylactic inoculations have also been employed against cholera and against plague. These attempts to raise the immunity of an animal before infection, and thus to enable it to resist the infection better than one that has not been vaccinated, are thoroughly logical and most promising, and they seem to me to be the proper sphere of vaccine work. It must, however, always be remembered that there is no such thing as absolute immunity and that the increased immunity afforded by the vaccines can always be broken down by a sufficiently large dose of the bacteria.

Of late the attempt has been made on a gigantic scale to employ vaccines not merely as a prophylactic measure, but also in the treatment of disease (these vaccines being composed of the dead bodies of the bacteria with their toxins). This is quite a different principle, however, from that on which vaccines were first introduced, and when it is proposed to rely on this treatment for the recovery of those wounded in war the matter requires very careful consideration. I have always felt rather sceptical as to the possibility of raising the immunity by this plan in cases where the disease is actually in progress. The fact that the disease is present shows that the natural immunity of the body has been more or less overcome, and the general view is that this has been brought about by toxins produced by the invading organisms and absorbed into the system. If this be true, the question very naturally presents itself, How can this immunity be restored by the injection of more toxins of the same kind? I can see no essential difference between the absorption of toxins from a wound and the injection of the same toxins from a bottle. If the quantity absorbed from a wound has broken down the resisting power of the body, how can it be restored by the subsequent injection of more toxins from a flask? I know that bacteriologists try to defend their position, but the arguments put forward in its support are purely theoretical and very obscure.

What support is there from clinical experience in favour of the employment of vaccines for treatment as apart from prophylaxis? Just think how many millions of vaccine injections have been made in the course of the last few years, and in how very few cases we can definitely recognise an immediate and marked improvement, as we ought to do if the treatment is to be justified. Think also, how often we are in doubt whether such improvement as occurs in the course of the treatment is due to the vaccine or is a natural result of the actions of the body. Think again in how many cases (the vast majority, indeed) there is no apparent action at all. I have used vaccines extensively (employing the services of bacteriologists for the

purpose, so that I should not feel that I had not been carrying out the treatment properly), and I have in only two or three cases seen any result which I should not have expected without their use. I have seen lesions getting well in one part of the body and yet, while still under vaccine treatment, fresh lesions breaking out in other parts of the body, and I have also seen bad and even fatal results follow the use of vaccines. To follow out this matter would, however, lead me far from my subject matter to-day, and all I would say as regards the place of the first method in the case of wounds in war is that while I would welcome vaccine injections as a prophylactic measure, I think they are very broken reeds to trust to once the organisms have established themselves in wounds.

Destruction of Organisms in the Body.

Let me now refer very shortly to the second point, of which the chief outcome is chemotherapy, the principle of which is to destroy the organisms by drugs after they have established themselves in the body.

Intermediate between (1) and (2) we have the use of antitoxic sera. Here antitoxins are introduced into the blood which destroy or neutralise the toxins of the bacteria, and the latter, when deprived of their weapons, soon fall an easy prey to the defensive arrangements of the body. The typical example of this is antidipteric serum, which, if given early enough, leads to very rapid arrest of the disease in a way which is not seen in vaccine therapy. In the case of tetanus the antitetanic serum seems also to be very beneficial in some cases, if used immediately after infection.

As to the direct destruction of bacteria by chemical substances or chemotherapy, we have imperfect examples of this in the treatment of malaria by quinine and of syphilis by mercury, and still more definitely in the treatment of syphilis by salvarsan. Whatever may be the value of salvarsan as regards the complete cure of syphilis the immediate effect is most striking and is evidently the ideal to be sought for in the medical treatment of any infective disease. Unfortunately, this form of treatment has not as yet been extended to the infective diseases with which we are at present concerned. If it were it would solve all our difficulties, and it would not be necessary for us to discuss the brutal methods which I felt it to be my duty to recommend at the meeting of the Medical Society last November¹ and which I am afraid I must again to a certain extent emphasise to-day. I sincerely hope that Professor Ehrlich, who, whatever may be thought of German Kultur in general, is the great pioneer in this work and to whom it would be difficult to find a successor, will still be able to go on with his work and will not be crippled in health or opportunity by this war. I may be prejudiced, but I look on Professor Ehrlich as the greatest medical asset that the world possesses at the present time.

The Disinfection of Wounds.

We are thus left with the only method of dealing with these conditions which we possess at the present time—viz., to attempt to destroy or prevent the growth of the organisms responsible for septic diseases before they have established themselves in the wounds, an attempt which we may speak of shortly as the disinfection of wounds.

LISTER'S METHODS.

You may remember that in my paper at the Medical Society last November I traced the history of the disinfection of compound fractures in Lister's work, and I may shortly repeat what I said.

His *first* plan was to introduce impure liquid carbolic acid into the wounds, stir it up with the blood, and leave it there, painting a little of the acid on the surface of the blood clot from time to time. The result of that plan was the complete revolution of surgery; his compound fractures behaved like simple fractures, there was no inflammation, suppuration, or sloughing, and none of the septic diseases such as phagedæna, erysipelas, pyæmia, &c., which were so common in his wards up to that time. What also struck Lister as most extraordinary, and what he was always remarking on, was that tetanus also disappeared, although it had been previously quite common in his wards. He had no idea until many years later that tetanus was an infective disease, but he frequently remarked that suppuration was somehow or other concerned with its onset because he had had no cases since he ceased to have suppuration in his wounds. Had the effect of undiluted carbolic acid been to cause extensive sloughing and to favour the growth of pathogenic bacteria, as some of our workers in laboratories tell us is the case, Lister's experiments would have failed and been abandoned and the revolution in surgery might not even yet have taken place.

The *second* stage, after Lister had given up the use of the undiluted carbolic acids in wounds, was to wash out compound fractures very thoroughly with 1 in 20 carbolic lotion, a catheter being attached to the syringe and passed into all the recesses of the wound, so that no part should escape the action of the antiseptic. It was found, however, that the results were not so uniformly good as in his original method, especially if the wounds were much soiled, and so his *third* plan was, in addition to washing out the wound with 1 in 20 carbolic lotion, to clip away the soiled tissues and apply undiluted carbolic acid to those parts. This is the plan which I have used for years and which has proved very satisfactory. Under the present circumstances in the field, however, I suggested a *fourth* plan—viz., in addition to clipping away the soiled parts, to apply the undiluted carbolic acid to the whole surface of the wound, opening it up if necessary.

My main idea in making this suggestion was in order to ensure that the whole surface of the wound should be subjected to the action of the antiseptic, and that no recesses should escape, as might very easily be the case if the wound were only syringed out. A further idea was that the carbolic acid might, so to speak, "pickle" the tissues and so prevent the growth of micro-organisms in them till such time as the defensive action of the tissues had come fully into play. That the procedure is a severe one and open to several objections I readily admit; the great objection, to my mind, being the risk, in the case of large wounds, of absorption of the carbolic acid to a disagreeable and even dangerous extent. At the same time, considering the evils of sepsis, this risk, which is not really very great, is worth taking if no better way can be found. Whether the plan can be modified in the light of the facts which I shall bring before you to-day is a matter which only experience can decide.

¹ THE LANCET, Nov. 21st, 1914, p. 1185.

DIFFICULTIES IN DISINFECTION OF GUNSHOT WOUNDS.

Some surgeons take a hopeless view of the disinfection of gunshot wounds and think that disinfection is impossible of attainment. That it is quite possible and comparatively easily obtained in accidents in civilian practice is a fact which cannot be denied. Why, then, should gunshot wounds be so hopeless? I think the idea is probably founded on experiments by Lagarde and others carried out a good many years ago. In these experiments it is stated that in gunshot wounds in animals, where the bullet is travelling at high velocity, particles of gunpowder may be driven into the tissues which form the sides of the wound to as great a depth as 17 millimetres and presumably bacteria might also be driven in to the same extent, in which case no amount of syringing out of the wound with antiseptics could affect them. I cannot argue this matter fully here, but I may say that the experiments, so far as I read them, are not convincing and I am not prepared to accept them without fresh and careful repetition.

A further reason given is that the sides of the wound are so deprived of vitality that they must slough. But dead tissue in a wound does not slough if the wound is aseptic; indeed, we constantly put dead substances into wounds, such as ligatures of all kinds, pieces of bone, &c., and they do not separate if they are aseptic. In many accidents in civil practice the tissues are equally badly contused, and yet if disinfected early and thoroughly the wound follows an aseptic course and the bruised tissues do not slough. Sloughing of bruised tissues is due to infection of these tissues. Anyone who followed the course of the bullet wounds in the South African War and remembers how frequently they healed without sloughing or suppuration will, I think, doubt the soundness of the view that gunshot wounds must slough and that bacteria are driven into the tissues to such an extent that sepsis must occur.

A third point which is being urged just now is that almost immediately after infection the infective organisms may be found in the blood of the heart. This may be true as regards guinea-pigs and bacteria which produce general diseases, but I want some further confirmation of it in regard to man and local diseases such as those we are dealing with. Even if it were correct in the case of man that some organisms do find their way from the wound to the heart very quickly, it is not these silly young Cupids that one has to fear in the case of septic wounds; they very quickly suffer the fate of unrequited love. It is the slim old bacteria that establish themselves in the wound, dig themselves in, and then proceed to pour out their toxins, that one has to guard against.

I quite realise, however, that there are many difficulties in carrying out the thorough disinfection of wounds in war, but I cannot believe that disinfection of these wounds is impossible, and I will not believe it till I have tried thoroughly myself and have failed.

In my paper at the Medical Society I especially referred to two great difficulties which stood in the way of any thorough disinfection of the majority of gunshot wounds. The first was the large number of cases which may come under treatment at any one time. Sir Anthony Bowlby has rightly laid great stress on this point in his interesting paper in a recent number of THE LANCET.² In

November I could only suggest that the cases should be sorted out, and that the compound fractures and joint injuries should be dealt with first and as soon as possible, leaving the others to take their chance as regards disinfection.

The second point which I emphasised was the length of time which might elapse between the receipt of the injury and the patient's arrival at a suitable place where thorough disinfection could be carried out, and the consequent failure of any attempt at disinfection owing to the growth of bacteria in the wound in the interval which elapses between its infliction and the reception of the patient at the dressing station or field hospital. With regard to this point I made one or two tentative suggestions, but they were very feeble, though they showed in what direction my mind was working. I said that we had been trying at Chatham to make soluble bougies or suppositories containing carbolic acid which might be pushed into wounds and delay the sepsis, or that, as an alternative, we might push in swabs soaked in iodine and leave them there; but I made no definite suggestion, for the simple reason that I had not worked it out and had no definite facts to go upon.

COMMITTEE OF INVESTIGATION: NATURE OF THE PROBLEM.

I have, however, taken up this problem very seriously since that meeting, and at the suggestion of Sir Arthur May, the Director-General of the Naval Medical Service, have formed a little committee consisting of Fleet-Surgeon Bassett-Smith, the well-known bacteriologist in the Naval Medical Service, Mr. Arthur Edmunds, who has worked with me for years, and who is also attached to the Royal Naval Hospital, Chatham, and myself. I may say that I have been most fortunate in the choice of my coadjutors; they are both men with great scientific knowledge, most industrious, and most ingenious. As far as I am concerned, it has been a great delight to me to go back to laboratory work and experiment again. The work has been done under the auspices of the Naval Medical Service, and the Director-General has given us every assistance that we wanted. It was done partly in the laboratory of the Royal Naval Hospital, Chatham, and partly in Dr. Bassett-Smith's laboratory at the Royal Naval College, Greenwich. We have to thank Sir Arthur May and also the staff at the Chatham Hospital for their most cordial help, and especially Staff-Surgeon Dudley, who has charge of the laboratory there. To-day I propose, with the consent of the Director-General and of my colleagues, to make a preliminary communication on our work, and to mention some of our experiments, and I hope you will remember that though I speak, what I say is the result of our joint work and not of my own alone. The more detailed report of the work, which is by no means completed as yet, will be published in the next number of the *Naval Medical Journal*.

The problem which we set ourselves was whether it was possible to introduce an antiseptic into a wound soon after its infliction which would remain there, diffuse in the blood and tissues, and inhibit the growth of the bacteria till such time as the wound could be thoroughly disinfected.

I think I can make the meaning of the problem clear if I give you an illustration, and as we are dealing with war I shall make it a warlike one. The enemy has established a battery at a certain point not accurately known, but evidently in connexion

² THE LANCET, Dec. 19th, 1914, p. 1427.

with a definite field or wood; that battery is inflicting, or is likely to inflict, great damage on our forces, and we must try to destroy it if possible. Our gunners proceed to throw shells over the suspected area, searching it thoroughly from side to side and from front to back; but it may quite well happen that they may plough up the whole field without injuring the battery or the gunners at all, because the latter are hidden away in some quarry or ditch and thus escape the shells. Just in the same way, we may syringe out a wound with antiseptic lotions without rooting out the bacteria, for they may be lying safely protected by a piece of bone or tissue or blood clot, and that is the reason why I advised opening up the wounds if necessary and applying the antiseptic methodically to the whole surface of the wound. And just as a field may be spoilt uselessly by the guns, so the syringing may damage the tissues without accomplishing its object, and may only enable the bacteria to get a firmer hold.

Now I suppose we all dream about various things at times—at any rate, I know that I do—and I have often thought that if I were writing a sixpenny romance on war I would make our gunners use shells containing some anæsthetic substance heavier than air which would diffuse along the ground and search out and anæsthetise the enemy, however well they were hidden. They and their guns could then be carted away at leisure. How furious it would make my noble and illustrious namesake if he found that his best troops were carted off the field and woke up to find themselves prisoners of war without a scratch on them!

Now I think that something of this kind would be the best way of attacking the bacteria in these wounds—that is to say, instead of syringing out the wound, which if done in a hurry or incompletely is futile—to introduce an antiseptic into the wound and leave it there to diffuse over the whole wound and inhibit the growth of the bacteria till the patient can be brought to the field hospital. It was with that idea in my mind that I spoke of bougies or iodine in November, and that is the problem which we set ourselves to solve.

ACCOUNT OF INVESTIGATIONS.

In working out this problem we had to consider various points. For example, we had to devise a method of estimating the diffusibility of antiseptics in blood clot and their action on the bacteria present in or on that clot. We soon found that their diffusibility and activity varied much according to the medium in which they were present and various other circumstances.

This led us to the question of the form in which the antiseptics should be used in wounds, and we then had to test the action of a variety of antiseptics in various media so as to find one suitable for our purpose.

Again, we had to study in what strengths these antiseptics could be introduced into and left in wounds, and further, we had, as far as possible, to test the action of the antiseptics which seemed most suitable for our purpose, in animals and in man. This last part of our research is still very incomplete, but we have learned a good deal about antiseptics which we did not know before, and therefore I hope this short preliminary communication on our work will not be without interest to you. At the same time, I wish you to understand thoroughly that it is really preliminary. All sorts of lines of research are still occurring to us, and I

would not say anything about it just now were it not that the matter is very urgent and that we have arrived at a point when it is necessary to test our results on actual wounds. Further, we shall no doubt have the benefit of various criticisms.

Media and Antiseptics.

I may, in the first instance, refer to the medium in which the antiseptics should be introduced into wounds in order to delay the growth of bacteria till the wound can be properly attended to. An essential point is that the antiseptic should remain in the wound and not escape from it at once; it is not a transitory action but a more or less continued one that is required. Hence it seems evident that antiseptics in a fluid form will not answer the purpose, for they will run out of the wound almost at once, and their effect will only be momentary. For this reason, therefore, watery, alcoholic, or oily antiseptic solutions were discarded, however efficient they might be from an antiseptic point of view. This left us with various pastes or ointments, and powders. As regards the latter, it would be very difficult to introduce powders into the recesses of a wound, and besides some of the most efficient antiseptics do not occur in the form of powder. Hence we chose pastes, and we have made a large number of experiments with the view of deciding what would be the most suitable basis with which to combine the antiseptic. I will show you presently an example of the behaviour of antiseptics according to the bases with which they are combined, and will make some remarks on this point, but in the meantime I may say that, as far as we can judge at present, the most suitable basis from every point of view is one consisting of six parts of lanoline to one part of white wax. I may say that in the preparations which I shall now show you in reference to the question of diffusibility of antiseptics the latter were combined in varying proportions with this base unless I state the contrary. We have, however, also tested the diffusibility and activity of several antiseptics in liquid or solid form.

The following were the chief substances tested: Carbolic acid. Tricresol (o.m.p. cresol, as Martindale labels it). This consists of the three cresols—ortho-, meta-, and para-cresol—which have very nearly the same boiling point and pass over together in the distillation of coal-tar products. Various proprietary substances which are used by surgeons in which the tricresols or allied substances form the active agents, but are mixed with other products of distillation and with varying quantities of soap so as to form an emulsion. Such were izal, cyllin, hycol, and lysol. Liquor cresolis saponatus (or English lysol made with pure redistilled tricresol, Martindale). Bichloride of mercury. Iodine. Salicylic acid. Salicylic and boric acids (1 to 3), a powder much used in the Russo-Japanese War. The double cyanide of mercury and zinc. Paraform. Turpentine. Various essential oils, especially oil of origanum, oil of cinnamon, and oil of eucalyptus. Alcohol. Various colloidal substances (mercury, silver, gold, selenium). Balsam of Peru, friar's balsam, and Dr. Mencièr's embalming fluid.

We have tested their diffusibility and inhibitory power as regards growth, and also the antiseptic power (i.e., the power of actually killing the bacteria) in blood clot and also on nutrient agar. As a matter of fact, we find that the diffusibility and antibacteric power of most of these pastes are much the same in nutrient agar as in blood clot, and for

demonstration purposes agar is far more convenient. Hence, on the present occasion, I shall show you some of our agar preparations.

Description of Methods.

Speaking generally, the plan which we have ultimately adopted as regards agar, is to place the antiseptic paste to be tested on the bottom of a Petri dish underneath a slab of nutrient agar and to paint the upper surface of the agar with an emulsion of bacteria of various kinds according to circumstances. We were then able to judge of the diffusibility and activity of the antiseptic by observing the growth or absence of growth of the bacteria which we had planted. Now a comparative test is only of value if all the conditions are exactly the same, and I think we have ultimately worked out a satisfactory method. We always use the same quantity of the paste by weight, either half a gramme or one gramme as we wish. This is placed on an ordinary microscopical cover-glass, either $\frac{3}{4}$ or 1 inch in diameter, which is applied to the centre of the under surface of the slab of agar. In this way the antiseptic is applied to the same definite area ($\frac{3}{4}$ or 1 inch) of the agar in all cases. Where fluids have been tested they have been put into a small paraffin cell containing pieces of filter paper and always in definite quantities.

The slabs of agar must also always be of exactly the same thickness, and here we had our greatest difficulty. We began by pouring the agar into a Petri dish, till, as far as we could judge, we had got the proper depth of agar, and then allowed it to solidify and turned it out into another Petri dish in the centre of which the paste was laid. After all, however, this was only guesswork; the table might not be level and one side of the agar might be thicker than another, and besides we could not always be certain that we had put the same amount of agar into each dish. This difficulty has been overcome in a very ingenious manner, and though when two or more men work together it is not usual to refer to any one man's share in particular, still in this instance the arrangement is likely to be very useful in similar experiments in future, and therefore I think I ought to say that it was devised by Mr. Edmunds, and I shall speak of it as Edmunds's cell. (Fig. 7.)

To make an Edmunds's cell you take two square pieces of glass, a brass ring of known thickness (we generally have used one $\frac{1}{4}$ inch thick), the ring being incomplete in one part, and two or three broad paper clips. First sterilise a glass plate in the flame and then lay it down on a dish, then similarly flame the interior of the brass ring and lay it down on the glass, then flame the other piece of glass and lay it over the brass. Bind these together by the paper clips and you have a cell with an opening at one part through which the melted agar can be poured and left to solidify. When the agar has solidified the cell is laid down flat, the clips removed, the upper glass plate and the brass ring lifted off, and then we have the slab of agar lying on the lower glass plate. The cover-glass with the paste is now placed on the centre of this slab, with the paste next the agar, and then the lower part of a Petri dish is inverted over it, the whole turned upside down, and with a little manipulation the slab is transferred to the dish. A thin emulsion of the bacteria to be employed is previously made and is now brushed over the whole surface of the agar with a camel's hair brush. Finally, a little fluid agar is run round the edge of the slab, partly to fix it to the dish and partly to prevent the escape of vapour should the antiseptic to be tested be volatile.

As regards bacteria, we have chiefly employed the ordinary pus organisms, the staphylococcus pyogenes aureus, but we have used micrococcus prodigiosus and also bacillus subtilis so as to study the effect on spores. It will be very interesting when we have time to study other organisms. The Petri dish thus prepared is placed in an incubator at the body temperature and observations made from time to time.

Results of Experiments.

I shall now show you some of the results, and first we will take a series in which the surface of the agar was brushed over with an emulsion of staphylococcus pyogenes aureus, which will show you the effect of various antiseptics on the growth of these organisms, the antiseptics being incorporated in the lanoline and wax base.

The first specimen which I show is a control where everything has been done as I have said, except that no paste has been applied, and you will see that the whole surface of the agar is pretty uniformly dotted with colonies of the staphylococci. (Fig. 2.)

As a marked contrast with this I show you next a plate where a paste containing 30 per cent. of cresol has been used, and you will see the large clear area in the centre where no growth has occurred and the very narrow fringe of small colonies around the edge of the agar. The central space is clear because no bacteria have grown there, and the extent of the clear space indicates the diffusibility and the activity of the various antiseptics when present in this particular basis (lanoline and wax). I shall have a good deal to say presently about the significance of this clear space and also about carbolic acid and tricresol, and I shall therefore leave this and the allied antiseptics to the last and show you, in the first instance, the action of various other antiseptics. I may, however, show you a series of the carbolic acid specimens from 5 per cent. up to 30 per cent. (Fig. 8) so as to illustrate the value of the method, and you will see that as the strength increases so the effect in arresting the growth also increases. In this series only half a gramme of the paste has been used so as to show the contrast of the various strengths better, but in the specimens which follow the amount has been one gramme.

Iodine.

In the meantime I shall pass on to other antiseptics, and in the first place I show you various specimens of the effect of iodine, which is so popular at the present time. I here show you plates where the paste contained 2 per cent. and 6 per cent. of iodine. (Fig. 1.) There was no use in going higher because even these pastes cause marked irritation of the skin, and when we reach 10 per cent. the paste left on only for 2½ hours caused almost complete destruction of the skin, so that iodine of that strength is clearly unsuitable as an application in wounds. Here you see that the iodine has not diffused at all, and that luxurious growth has occurred over the whole area just as in the control dish. I would especially call your attention to the plate where 6 per cent. iodine paste has been used, where you see that the growth is actually more luxuriant over the iodine than elsewhere. At first sight you might think that the organisms painted over the surface had run down and collected in the middle of the slab, but as a matter of fact the centre of these slabs of agar is the highest point on account of the cover-glass and ointment placed behind them. In these specimens the solid iodine has been mixed up with the lanoline and wax basis, and that might be the reason for its failure, and therefore we have gone further into the matter.

In the next plate which I show the iodine was mixed with iodide of potash in the ordinary proportions so as to aid its solution, but here also there is still no action. Again I show you a specimen where the ordinary tincture of iodine of the British Pharmacopœia has been used without any ointment basis, pieces of filter paper being saturated with the tincture and applied in the same manner as the paste, but still no growth has occurred.

I must say that these results have surprised me very much, as I was always under the impression that iodine was quite a useful antiseptic, though I

knew that it was not so good as was generally supposed. However that may be, it certainly does not show the diffusibility and activity which many other substances do, and I am afraid that we must therefore come to the conclusion that iodine is useless for our purpose. Certainly the clinical results in wounds in war, so far as they have come under my notice, coincide with these experimental results, for I have had several very septic cases which I have been surprised to learn afterwards had been freely treated with iodine soon after their infliction and shortly before I saw them.

Alcohol (on Filter Paper).

Some disbelievers in iodine have, I understand, expressed the opinion that any good effect of the iodine solution was due to the alcohol, but I show you here a plate where absolute alcohol has been used and where uninterrupted growth has gone on. (Fig. 2.) This is interesting, because it is not uncommon to see needles, &c., especially hypodermic needles, "disinfected" with methylated spirit.

Other Antiseptics Tested.

Paraform, 5 per cent. in paste (Fig. 3).—Here the result is good; there is a clear area beyond the cover-glass of $2/5$ to $3/5$ inch in extent. Immediately outside this area the colonies are large. As you will note, this is a small percentage of paraform, but I doubt if anything stronger could be employed in a wound, if indeed this percentage would not be too strong.

Double cyanide of mercury and zinc, 10 per cent. in paste.—This shows no action. Dry cyanide powder placed under an agar slab also causes no inhibitory effect, but if the powder is moistened with a little water, as was done in this next specimen, the inhibitory effect is very marked. I confess that I do not as yet understand this, but we are going into the matter. It is possible that there may be some dissociation of the double cyanide, but we shall see. In the meantime, however, I would warn those who wish to use the double cyanide in wounds that they must not put it into a lead vessel, for the lead is rapidly attacked and cyanide of lead is formed which is poisonous.

Bichloride of mercury—(Fig. 4) 0.2 per cent. in paste (= 1 in 500). Here we see a clear area beyond the cover-glass varying from $1/8$ to $1/4$ inch. Note that the colonies are large up to the edge of the clear area.

In the following specimens the antiseptic was combined with the lanoline and wax paste in the proportion of 20 per cent.

Salicylic acid.—Over the area of the cover-glass the surface is fairly clear, but shows scattered colonies. Free growth extends quite up to the cover-glass.

Japanese powder (Salicylic acid 5, boric acid 15, lanoline and wax base 80).—This plate shows very little inhibitory action, no doubt because the percentage of salicylic acid is too small and the boric acid is inert.

Oil of turpentine.—Free growth, no inhibitory action.

Oil of origanum.—The centre is clear, but in the immediate neighbourhood colonies are dotted all over, but it is comparatively clear for about $1/2$ inch. Free growth beyond.

Oil of cinnamon.—Very good, $3/5$ to $4/5$ inch clear area outside the area of the cover-glass.

Oil of eucalyptus.—No interference with growth.

Izal.—Colonies right up to and overlapping the area of the cover-glass.

Cyllin.—Somewhat larger clear area, but separate colonies are found right up to and overlapping the area of the cover-glass.

Hycol.—Better. Comparatively clear for about $3/16$ inch from the cover-glass, but scattered colonies to within $1/8$ inch of the centre.

Lysol.—Clear area about $1/4$ inch beyond the cover-glass.

British Lysol (Fig. 5).—(Liq. cresol. saponat.—Martindale). 20 per cent. paste. Large clear area; quite good.

Frian's balsam (pure).—Free growth. No inhibition.

Balsam of Peru (pure).—Clear circle $3/8$ inch beyond centre.

Dr. Menoïre's embalming solution (pure).—Free growth. No inhibition.

Colloidal mercury, selenium, copper, and silver.—No inhibitory effect.

We may now pass on to *carbolic acid and tricresol*. I have already shown you a series of dilutions of carbolic acid in small quantities, but I may now show you a 20 per cent. paste of carbolic acid (Fig. 6) where one gramme has been used, and then a 30 per cent. one. I may also show you a similar series with tricresol. You see that the results are practically the same with tricresol as with carbolic acid, and they are quite constant.

Significance of Clear Area.

Let us now study these preparations a little more carefully, and especially the meaning of this clear space. In the first place, it indicates that no growth has occurred in that area, and not only so, but that there never has been any growth, or at any rate not since a very short time after the preparation of the slide. In other words, the antiseptic has been able to diffuse so rapidly that it has checked the growth of the bacteria which were sown on the surface before they had formed colonies visible to the naked eye or even under a low power of the microscope. If one examines such a plate under a low power of the microscope, say with a 2-inch lens, 3 hours after inoculation, one can already see the colonies quite distinctly towards the periphery of the agar, but none can be detected towards the centre, in the area which will subsequently remain clear. In rather less than 5 hours after the preparation of the plate the colonies can be perceived with the naked eye. This will give you some idea of the extraordinary rapidity with which these organisms grow. From this we learn that at some period of time within 3 hours after the preparation of the plate, and probably a good deal less than that, the antiseptic has penetrated through $\frac{1}{4}$ inch of solid agar in sufficient amount to arrest the growth of the bacteria; indeed, seeing the extent of the clear area, it must have penetrated to a greater distance than $\frac{1}{4}$ inch. Thus you see the value of this clear space as an index of the diffusibility and activity of an antiseptic, and from the series of specimens already shown you see how differently the various substances which we have tested act.

There is another point which I wish you to note in this preparation (the carbolic acid or cresol plate)—viz., that the colonies at the edge of the clear area are quite small and that they increase in size as they lie further away from it. From this it is clear that the antiseptic did not cease to penetrate at the end of two or three hours. It is true, it only got through in amount sufficient to check growth before colonies had formed in the area shown by the clear space, but it continued to come through to a greater and greater distance, and as it came through it arrested the growth of colonies which had already become visible. All antiseptics, however, do not act in this way. Contrast the appearance of the paraform slide and several of the others which I have already shown. There you will see that the colonies at the edge of the clear centre are large—indeed, sometimes as large as any outside, showing that there was no continuance of the diffusion of the antiseptic; evidently the full amount came through quickly and the full effect was obtained in the first three hours. The continuance of the diffusion is a very important point and one in favour of

cresol and carbolic acid. I think we may therefore conclude that when carbolic acid or cresol is combined with this base a certain amount is stored up and only parted with slowly, whereas in other cases there is no such storing up, the antiseptic passing through quickly and exercising its full effect at once. We are inclined to think that it is the wax to a greater extent than the lanoline which holds up the carbolic acid, because the clear area is larger where the basis is lanoline alone than with the lanoline + wax base. I shall, however, show you immediately a series illustrating the effect of different bases, and you can note this point.

Evidence of Death of Bacteria.

Now another question naturally arises in looking at these barren areas. Are the bacteria, which are planted on the surface, still alive, or have they been actually killed, and, if so, how soon are they killed? You will always find that in cases where 20 per cent. or more carbolic acid or cresol is employed, if you make a cultivation from the centre of the plate over the cover-glass area 24 hours after the commencement of the experiment, no growth takes place, showing that the bacteria have died. We have spent a good deal of time in going into this matter.

In order to ascertain precisely what happens we have drawn a series of circles, $\frac{1}{4}$ inch apart, on a piece of paper. These circles have been numbered from the centre, 1, 2, 3, &c. The Petri dish is placed on this paper so that the centre of the cover-glass is over the centre of the circles. The 1-inch cover-glass occupies circles 1 and 2, and then we have the further circles 3, 4, 5, and 6 at $\frac{1}{4}$ -inch intervals from the edge of the cover-glass. At certain definite intervals of time cultivations have been made from the centre and from various circles around with the following results.

During the first three hours there is no evidence of death of the bacteria even at the centre, so that the absence of growth up to that time is purely an inhibitory effect. After that time one begins to get evidence of the death of the bacteria, in the first instance in the centre, then in No. 3 and No. 4. Here I show a specimen at the end of five hours, where you see that the growth from the centre is only slight, in No. 3 moderately luxuriant, and in No. 4 quite active. Next I show you a specimen from the same experiment 9 $\frac{1}{2}$ hours after its commencement. Here there are very few small colonies at the centre, a marked diminution in No. 3, and normal growth at Nos. 4 and 5. We have generally found that the central area is sterile after six to ten hours, and No. 3 becomes sterile next day and sometimes also No. 4. In one case cultures were taken 6 days after 30 per cent. cresol ointment had been applied, with the result that the centre, No. 3, and No. 4 were sterile. The line between Nos. 4 and 5 also appeared to be sterile at first, but after three days a few colonies appeared in the tube inoculated from that point. Note that the areas 4 and 5 show visible colonies, so that most of them had also died, and the few bacteria which survived had so suffered in health that it took three days before they had recovered sufficiently to grow. It is interesting to note that a cultivation taken from the centre of the 6 per cent. iodine plate three days after the experiment began grew luxuriantly. We have not had time as yet to test this point with other antiseptics or other bacteria, but it will be very interesting to do so.

One other point arises in connexion with these clear areas. Is the hindrance to growth permanent

or does the antiseptic ultimately disappear? Cresol and carbolic acid are both volatile, and it was interesting to see whether a time would come when the medium could again be inoculated with success. To test this we have taken dishes where carbolic acid, cresol, and formalin have been used, and after 21 days we have inoculated the clear space with fresh bacteria, but no growth occurred.

Effects of Different Bases.

I have already said that the results differ considerably according to the base with which the antiseptic is combined. We have made many experiments on this matter with which I need not trouble you, but I show you here a series of 20 per cent. carbolic pastes in five different bases. You will see that the greatest diffusion is obtained with pure lanoline and the least with a paraffin base, the latter being only half as great as the former. The lanoline when mixed with carbolic acid is, however, too diffuent, and besides, it is much more pungent and would irritate the wound and the skin. The addition of wax to it lessens its activity by about one-quarter, but it does not irritate the skin and only requires the introduction of a little more into the wound to obtain the same effect. The greatest diffusion in the carbolic series is obtained with undiluted carbolic acid and the same is the case with cresol.

Imitation of Conditions of a Wound in War.

We have also tried in various ways to reproduce the conditions of a wound in war as far as possible. I may show two experiments.

Take a flattened flask (this was done as it shows better in the epidiascope than an ordinary one), introduce into it nutrient agar with which staphylococci have been thoroughly mixed. When it has set, punch a channel down it and introduce down that channel a piece of gauze or lint which has been soaked in the cultivation of bacteria. Then, by means of a syringe or pipette, put small quantities of cresol or of carbolic ointment into the agar in various directions and place the flask in the incubator.

As you will see in this experiment done five weeks ago and in which 30 per cent. cresol ointment was used no growth has taken place anywhere, while the control vessel shows active growth.

I also show you two similar vessels of gelatin done on Jan. 20th in which micrococcus prodigiosus was used and a piece of ordinary lint which was lying about the laboratory was put in and in the one in which 20 per cent. carbolic paste was used you see no growth. (We have since repeated the experiment with a massive blood clot and precisely the same result has been obtained.)

Spore-bearing Bacilli.

So far I have been speaking of experiments with non-spore-bearing bacteria, and especially with staphylococcus pyogenes aureus, but before I leave this part of the subject I may mention that we have also tried similar experiments with the spores of bacillus subtilis, and I show you one with 20 per cent. carbolic paste which shows a clear area as in the experiments with staphylococci. Tests have been made as to the vitality of the spores; for example, cultivations were taken from the centre, from space No. 3 and from space No. 4, 12 $\frac{1}{2}$ hours after the commencement of the experiment. On the following day there was no growth from the centre, but there was growth from No. 3 to a certain extent and quite copiously from No. 4. After a further 24 hours in the incubator there was still

no growth from the centre, but on the third day slight growth was evident which presently became quite copious. Apparently, though the spores had not been killed, they had been damaged, and took some time to recover their natural activity. We have not yet had time to pursue this matter so far as with staphylococci, but some interesting points as to the action on spores have been observed and are worth following up.

Scope of Investigations.

So much for a short sketch of our experiments with agar. I hope you understand thoroughly what their scope is. This is not a method to test whether a particular antiseptic will or will not kill bacteria, or in what concentration or after what length of time it will do so. For that you have the Rideal-Walker and various other methods, but these only deal with naked bacteria with which the antiseptic comes into immediate contact. The method which I have now shown you is, I think, a far more practical one because it enables us to study the action on bacteria at a distance and in different surroundings, as we have to do in connexion with the treatment of wounds. This method, which I believe is new, opens up quite a fresh line of study, and I fancy that, in following up the points raised by it, we shall have enough to occupy all our spare time while this war lasts. And it is quite possible that we may come across some better antiseptics or some better method of applying them in the course of our study.

The explanation of the diffusion is partly osmotic pressure and probably partly volatility of the antiseptic. Another thing also happens which affects diffusibility—viz., combination of the antiseptic with substances in the surrounding medium. This is probably the explanation of the result with iodine, which, though an active antiseptic when free in the presence of naked bacteria, has a marked tendency to combine with a great variety of substances which diminish or destroy its antiseptic qualities. Hence the reason why it does not diffuse, as an antiseptic, in blood and agar. (We have since found that one iodine plate prepared as above and covered with starch paper shows no starch reaction after 24 hours.)

Experiments on Blood.

Although I have been showing you agar experiments, we have done a number of similar experiments with blood clot—indeed, all our earlier work was with blood. In most of our experiments the blood was received into a long cylindrical vessel and allowed to clot. The clot is then turned out into dishes and cut in slices about half an inch thick, like a Swiss roll, and treated in the same way as I have already mentioned. In some cases a very thin layer of agar has been run over the surface of the clot, so that the colonies of the bacteria can be more readily seen than in the clot itself. I need not take up your time by narrating the experiments, but the results so far as we have gone are very much the same; certainly they are quite the same with the carbolic and cresol pastes and with iodine. The arrest of the growth of the bacteria and their subsequent death occur in blood clot as in agar, and the clot, where it is penetrated by the antiseptic, becomes firm and hard and unsuitable for the growth of bacteria. If a thick mass of blood clot is placed in a beaker and the carbolic or cresol pastes mixed up with it it becomes

a solid mass, and bacteria do not grow in it. A somewhat similar effect is produced by mixing blood with the double cyanide of mercury and zinc powder, but in one case which was tested micrococci were growing on the surface. Iodine in the form of a 6 per cent. paste does not check the growth of organisms in blood at all.

EXPERIMENTS ON ANIMALS.

We have not done much in the way of experiments on animals, because it was necessary to become pretty thoroughly acquainted in the first place with the general behaviour of antiseptics as regards diffusibility and activity, and that has taken up most of the time at our disposal. We have, however, done some experiments and can now take up the matter more systematically.

It is by no means easy to devise suitable experiments on animals, especially on guinea-pigs, which up to the present were the only animals at our disposal; and further, we have not, so far, got a very virulent organism which produces local suppuration in guinea-pigs without at the same time, in most cases, also setting up a general septicæmic disease. Guinea-pigs also have no subcutaneous tissue, so that the skin has to be raised so as to introduce the infective material, and when the wound is closed this material flows into the tissues beyond the region of the wound; in fact, it is practically a subcutaneous injection; or if a fluid is used, it runs out over the skin and may reinfect the wound at a later period. We shall, however, manage to overcome these difficulties.

The best organism that we have tried as yet is the bacillus pyocyaneus, which sets up suppuration and sloughing locally, but at the same time is very apt to get into and grow in the blood. We have, however, got some results with this organism which indicate that we are working in the right direction. To take one series, pieces of lint soaked in a virulent emulsion of bacillus pyocyaneus were introduced into subcutaneous pockets in seven guinea-pigs:—

(a) Control. The inoculation was followed by severe suppuration; the animal rapidly lost weight and was killed in seven days. Bacillus pyocyaneus was present in the wound.

(b) Tricresol paste (30 per cent.) was introduced into the wound immediately after infection. No suppuration for four days, and the animal gained weight; then began to lose weight and slight suppuration occurred. Wound opened and cleaned out, and lint removed; rapidly got well. Bacillus pyocyaneus found in the wound.

(c) Carbolic acid paste (30 per cent.) introduced immediately after infection. Same result as in (b), but no bacillus pyocyaneus found.

(d) Tricresol paste (30 per cent.) introduced 15 minutes after infection. Almost continuous gain in weight; no suppuration for four days. Recovered. Bacillus pyocyaneus not found in wound.

(e) Carbolic acid paste (30 per cent.) introduced 15 minutes after infection. Gain in weight and no suppuration for four days; then slight suppuration, but no bacillus pyocyaneus found. Recovery.

(f) Tricresol paste (30 per cent.) introduced half an hour after infection. Rapid loss of weight, suppuration, and necrosis. Animal killed. Bacillus pyocyaneus found.

(g) Carbolic acid paste (30 per cent.) introduced half an hour after infection. Rapid loss of weight, suppuration, and necrosis. Animal killed. Bacillus pyocyaneus found.

As regards tetanus and spreading gangrene, somewhat similar experiments have been performed with some highly infected earth which Dr. Bassett-Smith was able to produce through the courtesy of Dr. Dudgeon, of St. Thomas's Hospital.

The control animal died in three days from spreading gangrene, and *bacillus aerogenes capsulatus* was present in large numbers. The others died from tetanus from the third to the seventh day, but there was no gangrene, though both *tetanus bacilli* and the *bacillus aerogenes capsulatus* were present.

These experiments are being continued, but so far it seems as if the 30 per cent. pastes carbolic acid and tricresol prevented suppuration (*B. pyocyaneus*) for four days at least, longer than we required, while although tetanus appeared to be unaffected the action of the gangrene-producing organism was apparently checked. By the additional use of antitetanic serum it seems that the occurrence of tetanus may also be prevented. In no case was there any acceleration of the infection by the treatment. Further experiments will be reported later.

OBSERVATIONS ON MAN.

Looking over the specimens that I have shown you it will be seen that there are several antiseptics which evidently have considerable value from the diffusion point of view and which it might be worth while investigating in the case of wounds in war. Such are carbolic acid, tricresol, lysol, corrosive sublimate, paraform, oil of cinnamon, double cyanide of mercury and zinc, salicylic acid, and balsam of Peru. Of these, in all probability, paraform would be too irritating, while if much corrosive sublimate were left in a wound it might be absorbed in serious amount; they might, however, be of use for later dressings. It is clear, however, that the whole subject must be carefully worked out at the front. In the meantime, taking everything into consideration, it seems, so far as we have gone, that tricresol or carbolic pastes should be tried first in the strength of 20 per cent.

In connexion with the use of these pastes in wounds we tested their effect on the skin, and as Mr. Edmunds has a delicate skin and a considerable expanse of it, he was deputed to wear the various pastes for 24 or 48 hours. The 20 per cent. carbolic or cresol pastes did not cause any redness or irritation of the skin, but greater strengths left a reddish area, and it was evident that any greater strength would probably prove unsuitable. The cresol paste also seemed more irritating than the carbolic acid. We also tried various iodine pastes; the 2, 4, and 6 per cent. pastes caused marked redness and irritation of the skin after 24 hours, and this did not pass away for several days. We could not induce Mr. Edmunds to wear a 10 per cent. iodine paste for more than 2½ hours, and that burned a hole in the skin which took some time to heal. From that experience and from the failure of iodine pastes in the experiments with agar and blood clot it is evident that this antiseptic is of no value for our purpose.

Having decided on the paste, we tried to get some fresh wounds on which to try it. Unfortunately for our purpose, though fortunately otherwise, during the last three weeks there have been no fresh naval wounded at the Chatham Hospital, and hence we have not had the opportunity of testing it on actual war wounds. We have, however, had several cases from which we could form some idea as to the action of the paste in wounds. The following was the first case in which we tried the paste:—

1. The patient was a man who shot himself in the face and head. The bullet entered just in front of the mastoid process and ran upwards and forwards and came out at the

inner side of the forehead near the middle line. In its course it broke up the upper jaw and malar bone, leaving a large cavity full of pieces of bone, passed through the eyeball tearing it to tatters, and smashed up the lower and anterior walls of the frontal sinus. The fracture of the frontal bone extended into the nose, where also the dura mater was torn, but there were no cerebral symptoms at first. The remains of the eyeball were removed, and one small, quite loose fragment of bone from the supraorbital region. The 20 per cent. cresol paste was then freely introduced into the whole track and cavity of the wound. The patient lived four days and died of his intracranial injuries, but during that time there was no inflammation, or sloughing, or suppuration from the wounds; they were quite aseptic, and no bacteria could be found in pieces of blood clot examined on the second and third days. On the second day a cultivation was made from the end of the drainage-tube where it projected beyond the wound, and only six colonies of cocci were obtained. Naturally one would have expected some growth from that part, and it is surprising that it was so little. He developed symptoms of meningitis and died on the fourth day. On post-mortem examination suppurative meningitis was found, but there was no suppuration anywhere in the external wound where the paste had been introduced; indeed, although it communicated with the nose and with the tear in the dura mater, the blood clot was lying in it without any decomposition.

I may mention one other case which is also very instructive.

2. The patient had a bad crush of the thumb, practically destroying the vitality of the terminal phalanx and laying open the phalangeal joint. It was a machinery accident and the parts were very much soiled. Carbolic acid paste (20 per cent.) was at once squeezed into the wound and over the dirty skin before his admission to the hospital. When he arrived at the hospital an energetic temporary surgeon proceeded to clean up the wound and thus spoil the observation, but he was caught in time; the parts were dried and more paste was put in. The wound remained quite quiet, no pain, no suppuration, no temperature or constitutional disturbance. We know what a mess such a wound would have been in under ordinary circumstances—stinking, inflamed, swollen, and probably a good deal of constitutional disturbance. At length on the tenth day the surgeon who had charge of the case wanted to see what the condition of the terminal phalanx was, and so he set to work and cleaned out the blood clot and the skin. He found the greater part of the terminal phalanx dead but not smelling, and he applied ordinary dressings. Two or three days later inflammation set in and suppuration spread up along the tendon sheath. He therefore removed the end of the thumb and opened the sheath. My own belief is that had the wound been left alone the infection would not have occurred, the dead tip would have dropped off, and healing would have taken place without any infection. At the same time the result was very remarkable and encouraging.

Four days ago we had an accidental pistol wound of the buttock with fairly large wounds of entrance and exit. Carbolic paste was introduced, and so far there is no sign of inflammation or suppuration.

BEARING OF RESULTS ON TREATMENT OF WOUNDS.

So much for the facts which we have to bring before you. What are the chances of attaining our object? Recall what that object was: to find some means of averting sepsis in a wound for some hours, or at most a day or two, till thorough disinfection can be carried out. Nothing more. Now we have learned from laboratory experiments that quite a number of antiseptic substances are able to penetrate agar and blood clot to a distance of ¼ to ½ inch and still retain sufficient antiseptic power to prevent the growth of organisms, and that this penetration takes place in less than three hours. We have learned in guinea-pigs in the case of the virulent *bacillus pyocyaneus*—quite a different class of organism in its relation to the guinea-pig from the pyogenic cocci in their relation

to man—that the development of infection can be delayed for four to five days by these pastes provided the paste is put in early, within 15 minutes, and that when the wound is cleaned out at the end of that time healing rapidly occurs. From the first observation on man we learn that after one application of one of these pastes to a wound which has not been badly infected no signs of infection have occurred in that region for four days. From the second observation we find that no suppuration or other sign of infection occurred for ten days, although a great part of the tissue bordering on the wound was actually dead, and this was a much dirtier wound than the other.

I cannot but think that these facts point to the possibility that this part of the puzzle as regards the treatment of wounds in war can be solved satisfactorily, and that the danger caused by the delay in getting the cases to a place where proper attention can be given to the wounds can be reduced if not entirely removed.

I think the stage has now been reached when the matter must be worked out more thoroughly on man, and this can only be done at the front. I am afraid I shall not have the opportunity of doing so myself, unless there were a naval action in the Channel. So far, where the actions have been farther north, we have only got the wounded at Chatham a day or two after the injury. Indeed, the only way of getting at the naval cases at an early stage would be to go on board a destroyer or cruiser, but I confess I do not fancy knocking about the North Sea in a destroyer on the off-chance of having a scrap with the Germans. I hope, however, that the plan will be tried by those on board ship, and also by the army at the front. I need hardly say that we shall be only too pleased to show our work and impart our ideas to anyone who is going to work at this subject at the present.

I cannot help thinking, though it is perhaps only a hope, that by this plan we may attain more than a temporary arrest of sepsis, that in some cases we may even attain complete disinfection of a wound, rendering further measures unnecessary, but this, again, can only be worked out at the front. I doubt, however, if these problems will be solved by haphazard work of individual surgeons. Had I the authority I would set aside a small section of the front line with its own line of communications and its base hospital for the thorough study of the whole problem, and appoint a committee of a few men to investigate the subject and to follow up the cases. I say a small section of the front, because one would not want to be overwhelmed with wounded. I need hardly hint that if such a committee were appointed I should like to be one of the members.

CONCLUSION.

I must apologise to you for having taken up so much of your time to-day, but the subject of the treatment of wounds in war is one which has been a hopeless puzzle for centuries, and anything which can in any way, however slight, help to solve that puzzle is well worth the closest consideration. I have also to apologise for having brought you here to-day to hear a Hunterian oration and yet not giving you any oratory or saying anything about Hunter's work, but I am sure that if he had been alive to-day he would have been just as anxious to solve this puzzle as any of us are.

COLLOIDAL IODINE ASSOCIATED WITH SERUM TREATMENT IN TETANUS.

By DR. AUREGAN,

HEAD SURGEON OF THE HOSPITAL AT LANNION, FRANCE.

HAVING been placed in charge of the special tetanus department of a supplementary hospital containing 1100 beds, I had the opportunity of treating 23 cases of tetanus between September and December, 1914. At first I employed intraspinal injections of antitetanic serum in repeated doses; with this treatment the number of deaths preponderated over that of the recoveries. On the other hand, apart from tetanus cases, I employed colloidal iodine in my surgical department (250 beds) as a dressing for wounds,¹ in accordance with the principles laid down by Professor Bazy in the Beaujon Hospital.² Now it seemed to me that the tetanus patients, who had been subjected to serum treatment but had in addition received the above treatment, and whose organism had absorbed colloidal iodine owing to their wounds having been persistently in contact with this preparation,³ recovered in a markedly higher proportion. Since then I have systematically combined colloidal iodine treatment, both in the form of dressings and in the form of daily intramuscular injections,⁴ with serum treatment in tetanus. Tetanus patients who have been thus treated proved to have survived in a proportion of 68·8 per cent., a percentage that would appear to be distinctly higher than the average proportion of recoveries ordinarily obtained.⁵

I therefore consider it my duty to publish my cases at once, whilst at the same time I intend, with the collaboration of M. Viel and Dr. Revault d'Allonnes, to continue our researches on the association of colloidal iodine with serum in the treatment of tetanus.

1. Colloidal Iodine Employed both Internally and Externally in Combination with Serum Treatment.

CASE 1.—Patient sent to the tetanus department on Nov. 3rd, 1914, in a state of manifest tetanus, by Dr. D—. Wounded at Ypres on Oct. 29th. Shell wound of the left hip. Incubation period 5 days. The temperature has never reached 39° C. Pulse slow, never exceeded 115, and soon fell to 60. Firm trismus; biting of the tongue. This patient was brought to us in a state of absolute rigidity and with opisthotonos; frequent and intense convulsive attacks; spasm of the glottis of so alarming a type that he was prepared for tracheotomy; the operation could, however, be avoided. Deglutition was impossible for three days. The slightest attempt at deglutition brought on attacks of asphyxia. Treatment: The wound was dressed daily with colloidal iodine. Daily intramuscular injections of colloidal iodine. Intraspinal injections of antitetanic serum, 30 c.c. on the first day, 20 c.c. on the second, 25 c.c. on the third, and 30 c.c. on the fifth. Every three to four hours medicated enemata containing bromide of potassium 3 grm., chloral 5 grm. Subsequently the doses were reduced by one half, and after the fifth day hypodermic injections of bromide and camphor (aa. 1 grm.) in oil were substituted. Recovery in 15 days.

¹ A 25 per cent. oleaginous suspension, of medium coarseness, of electro-chemical colloidal iodine.

² *Revue de Thérapeutique Médico-Chirurgicale*, Feb. 15th, 1914; *Gazette des Hôpitaux*, March 19th, 1914; *La Clinique*, April 10th, 1914; *Comptes Rendus du Congrès International de Pathologie*, October, 1912.

³ The above-mentioned articles prove the extremely high diffusibility of colloidal iodine in the organism whether it be injected intramuscularly or merely applied to absorbing surfaces.

⁴ For intramuscular injections I have employed a 20 per cent. ultra-finely granular oleaginous suspension of electro-chemical colloidal iodine.

⁵ In no case was the diagnosis of tetanus at all doubtful; most of the cases had been sent to us by the medical officers of various departments in a condition of manifest tetanus.

CASE 2.—Patient of the tetanus section. Wounded at Ypres on Nov. 4th, 1914. Fracture of the right leg and the right elbow due to shrapnel bullets. Incubation period 16 days. The onset was slow but progressive. Six days before and three days after the appearance of trismus the temperature rose to 40° C.; it remained in the neighbourhood of or below 38°. The trismus was not very firm. The convulsions were not very intense, and mainly in the leg. Owing to the action of the risorius and of the face muscles, risus sardonius was well marked. Few clonic spasms; biting of the tongue; no visceral symptoms. Treatment: External and internal administration of colloidal iodine, as in Case 1. Wellcome's antitetanic serum, 10 c.c. hypodermically, when the first signs became apparent; 40 c.c. intraspinally on the following day. Chloral 5 grm. per diem and bromide by the mouth. The symptoms increased progressively until the fourth day, then diminished until they disappeared completely on the eighth day. In this case one might question as to whether one were dealing with a case of benign tetanus that has been subjugated by treatment.

CASE 3.—Patient sent to the department by Dr. D— on Nov. 12th, 1914, in a condition of manifest tetanus. Wounded at Ypres on Oct. 5th. The right leg had been pierced by a fragment of shell; penetrating shell wound of the right hand. Incubation period 6 days. On the 11th cramps in the wounded leg followed by a violent onset of very severe symptoms. Temperature fluctuating between 38° and 39° C., rising to 40° after each serum injection. Pulse varied between 110 and 140. Moderately marked rigidity of all the muscles of coördination, especially of those of the neck and jaw. Very violent and frequent convulsive seizures, the frequency depending on external stimulation. Biting of the tongue. From the fourth day onwards these crises of the external musculature became less intense and the intervals increased. On the other hand, splanchnic cardio-respiratory reaction set in; the respiration became noisy and gasping; during the pharyngeal spasms the face became cyanosed, froth issued from the lips, urine was passed involuntarily. Treatment: External and internal administration of colloidal iodine. Wellcome's antitetanic serum injected intraspinally; 40 c.c. on the day following the appearance of trismus; 40 c.c. of a French antitetanic serum on the third day; 30 c.c. of the same on the tenth day. Chloral; camphorated bromide oil. Asphyxia on the tenth day. Death was only avoided by immediate tracheotomy. Cannula removed on the fourteenth day. From this day forward the patient entered into convalescence as regards his tetanus; the incisors could be separated for 1 cm., the pupils and the eyes regained their movement. The symptoms now continued to ameliorate; three days after the onset only the slightest trace of trismus accompanied by unimportant irritation of the trachea and bronchia remained, the latter being the after-effects of the tracheotomy.

CASE 4.—Patient sent to the tetanus department by Dr. J— on Nov. 16th, 1914, in a condition of manifest tetanus. Wounded on Nov. 3rd at Ypres. Fistulous wound of the thigh due to fragments of shell. Incubation period 11 days. During the night of the 14th–15th the patient twice bit his tongue. On the 15th at 6 P.M. there was difficulty of deglutition, slight trismus. The course of the attack was slow but progressive. Temperature 30.5° C. on the 15th and 16th. Fixed risus sardonius; slight rigidity of the neck and trunk; no contractions of the limbs; no crises. Treatment: As in previous case. Rapid recovery. Normal temperature from the third day onwards; the risus sardonius and slight trismus persisted for another eight days. The same question arises in this as in Case 2: Are we dealing with a case of benign tetanus or with one in which the tetanus has been subjugated?

CASE 5.—Patient sent in by Dr. B— on Nov. 25th, 1914, in a condition of manifest tetanus. Wounded at Ypres on Nov. 18th. A piece of exploded shell penetrated at the outer border of the right scapula. He was a powerful muscular man. Incubation period 7 days. Fulminating onset. On the morning of the 25th towards 10 o'clock he manifested no symptoms of tetanus; he was chloroformed for an attempt at extraction; at 4 P.M. the spasmodic attacks were of extreme violence. Temperature 38.4° C.; pulse 80; opisthotonos; firm trismus, extremely violent crises of considerable duration and recurring every five minutes; biting of the tongue; glottic spasm producing asphyxia; violent colic

with diarrhoea; myosis. Treatment: External and internal administration of colloidal iodine. French antitetanic serum, 55 c.c. intraspinally on the first day; 40 c.c. on the third day; chloral; camphorated and bromide oil. After having moderated for 48 hours the temperature rose above 39° on the fourth day, the symptoms becoming aggravated at the same time. Syncope on the sixth day owing to arrest of the cardiac action; the patient was revived by artificial respiration and massage of the heart; he was able to speak a few words, but succumbed two hours later.

CASE 6.—Patient sent in by Dr. J— on Nov. 16th, 1914, in a condition of manifest tetanus. Wounded on Nov. 2nd at Ypres. Wounds: (a) On the right thigh three wounds from shell fragments, the two first forming a transverse fistulous track in the middle part of the thigh, one wound on the surface of the knee at the internal border of the patella, infected; (b) fistulous wound of the right forearm from shell fragment, fracture of the radius—splinters of bone were removed; (c) penetrating wound of the left cheek from shell fragment having traversed the jaw and broken a tooth. Special remarks: This patient received a hypodermic injection of antitetanic serum 11 days after he was wounded and three days before the onset of tetanic symptoms. Incubation period 14 days. Sudden onset, initial symptoms grave. Temperature 38.2° C.; pulse 90–100. Violent contractions of the masseters, the neck muscles, and those of the trunk and limbs; violent crises every eight to ten minutes; biting of the tongue; no glottic or vesical spasm. The tetanic symptoms improved from the fifth day onwards, but the temperature did not become normal until the fourteenth day. Treatment: External and internal administration of colloidal iodine; belated prophylactic hypodermic dose of 10 c.c. of French antitetanic serum as already mentioned; 50 c.c. administered intraspinally on the day of onset; chloral; camphorated bromide oil. One month later slight contracture of the face muscles still persisted.

2. Colloidal Iodine as a Wound Dressing Combined with Serum Therapy.

CASE 7.—Patient sent in by Dr. H— on Oct. 1st, 1914, in a condition of manifest tetanus. Wounded on Sept. 16th at Soissons. Transverse wound of the left leg; complete severance of the tendo Achillis; partial division of the tibia. On arrival there was copious fetid suppuration; much sloughing. Incubation period 11 days. Gradual onset. Temperature, wide declining fluctuations; maximum 40° C. on the fifth day and 38.5° on the onset of tetanic symptoms. Spasmodic symptoms; opisthotonos, biting of the tongue, difficulty in deglutition, glottic spasm. Treatment: The sinuous and very extensive wound, which exhibited loss of substance and suppuration, was sprinkled daily with a 25 per cent. suspension of colloidal iodine; compresses soaked in the same preparation were allowed to remain on the wound. The absorption of the metalloids, due to the finely divided state of the colloid, is such that the iodine can be detected in the urine 20 minutes after the preparation has been applied.⁶ Intramuscular injection of 15 c.c. of French antitetanic serum on the day of onset; 45 c.c. injected intraspinally on the fourth day; 15 c.c. intraspinally on the sixth day; chloral; camphorated bromide oil. Recovery from tetanus in 15 days. The wound continued to cicatrize in a normal manner.

CASE 8.—Patient in the tetanus section. Wounded at Maucourt (Somme) on Oct. 7th, 1914. Sinuous penetrating wound, due to exploded shell, in the lower and outer region of the left thigh; suppuration; shreds of military cloak removed from the wound. Incubation period 8 days. Gradual onset. Slight trismus on the evening of Oct. 15th. On the morning of the 16th the dental arches could only be separated for 2 cm.; no contractions of the neck and trunk muscles; deglutition easy, but twitching caused in the wounded limb. Temperature normal; pulse 96. Spasmodic seizures provoked by lumbar puncture. On the 18th pains in the viscera, violent colic, and inability to pass urine; the contraction of the sphincter of the bladder was such that it rendered the passage of a catheter uncomfortable. Treatment: Daily dressings with colloidal iodine. 50 c.c. of French antitetanic serum injected intraspinally on the 16th, and on the subsequent days in small frequent doses, 10 to 15 c.c.;

⁶ Tuffier: Paris Médical, 1913.

chloral; camphorated bromide oil. Protracted form; recrudescence of the crises on the seventh day; recovery could not be regarded as definitely attained until the fourteenth to fifteenth day.

CASE 9.—Patient in the tetanus section. Wounded at Ypres on Oct. 26th. Fistulous wound on the right side of the thorax; shell wound in the right thigh, emphysematous gangrene. Incubation period 12 days. On the morning of the 8th spasmodic attacks in the right leg, recurring every five to eight minutes; slight trismus. Temperature between 37° and 38° C.; rose to 40° after the first injection of serum. Slight opisthotonos; the spasms spread to the entire body; biting of the tongue. Treatment as in Case 8. Recovery after 10 to 15 days.

CASE 10.—Patient sent in by Dr. H— on Oct. 9th, 1914, in a condition of manifest tetanus. Wounded in the left arm by a shell fragment on Sept. 27th. Amputation at Villers-Bretonaux on Sept. 29th. Arrived at Rennes with trismus. Incubation period 11 days. After each injection of serum the temperature rose above 39° C. and dropped to 37° on the third day on each occasion. Pulse 130 to 140, poor. Trismus; intense opisthotonos; violent and frequent spasmodic attacks; biting of the tongue; profuse sweating. Grave cardio-respiratory type; attacks of asphyxia due to spasm of the glottis; tracheal obstruction. Treatment: As the stump exhibited a large bleeding surface it was sprinkled thoroughly with colloidal iodine and dressed with the latter. French antitetanic serum injected intraspinally, 50 c.c. on the first day, 30 c.c. on the third day, 20 c.c. on the seventh day, and 20 c.c. on the eleventh day. Course: The condition remained stationary and was grave and alarming for 15 days. A distinct transitory amelioration after each injection of serum, then recrudescence of the symptoms. Towards the fifteenth day distinct improvement, and complete recovery on the twentieth day. Two and a half months after the injury the stump was still suppurating.

CASE 11.—Patient sent in by Dr. D. H— on Oct. 27th, 1914, in a condition of manifest tetanus. Wounded on Sept. 9th. Shell wound at the lower supra-articular end of the left leg; the two orifices were very lacerated; splintered mass of bone; infected. Incubation period (?) 7 days. Temperature between 37° and 38° C.; pulse normal. Opisthotonos; trismus; moderately strong and frequent intestinal spasms; biting of the tongue; profuse sweating. Treatment: Immediate drainage. The drug treatment may be divided into two periods—(1) hypodermic serotherapy without colloidal iodine up to the tenth day; and (2) external application of colloidal iodine combined with administration of chloral. Course: The original condition remained unchanged and without exacerbation or any marked amelioration for about two weeks. Recovery was gradual, and was definitely reached on about the twenty-fourth day.

CASE 12.—Patient sent in by Dr. B— on Nov. 2nd, 1914, in a condition of manifest tetanus. Wounded at Ypres on Oct. 26th. Transfixing wound of the left thigh due to shell fragment. Incubation period 6 days. Gradual onset. Temperature 37° C. on the morning of his admittance to the tetanus ward, and remained so until the following evening; rise to 39° and 40° on the subsequent days. Pulse 120 on the third day, irregular. Opisthotonos; rigidity of the wounded thigh; biting of the tongue; profuse sweating; alarming and frequent glottic spasms—we were on the point of performing tracheotomy. Treatment: Wellcome's antitetanic serum injected intraspinally; 30 c.c. on the day of onset, 20 c.c. on the following day, 20 c.c. on the fourth day, and 30 c.c. on the seventh day. The absorption of the colloidal iodine must have been very limited, for the dressing consisted merely in applying compresses soaked in colloidal iodine to the orifices of the wound; chloral; camphorated bromide oil. On the eighth day the pulse-rate continued to increase and reached 140. To the phase of excitation of the centres there succeeded a new stage; absence of trismus, ability to open and close the mouth in an apparently normal manner, re-establishment of the palpebral and ocular movements. But swallowing and expectoration became impossible, either because the spasm of the glottis persisted, or because it had been replaced by paralysis of the pharynx and of the velum palati. Agony, in which symptoms of asphyxia and cardiac failure were blended. Death on the morning of the ninth day.

CASE 13.—Patient sent in *in extremis* on Nov. 2nd, 1914, by the head physician of Supplementary Hospital No. 79. Wounded at Ypres on Oct. 26th. Fracture of the right forearm by a large shell fragment which had remained in the wound; contused wound of the hairy skin; fracture of the right fibula by shell fragment; copious suppuration. Incubation period unknown; in any case less than six days. Temperature 39° C., but soon attaining higher levels on the subsequent days. Total and persistent rigidity of the trunk, the neck, and the limbs; attacks of cramp, especially in the fractured forearm; biting of the tongue; abundant and profuse sweating; acute pains in the epigastric region may be attributed to tetanus of the diaphragm; glottic and pharyngeal spasm leading to obstruction of the bronchia. Dread of every manipulation that may bring on a spasmodic attack. Treatment: On the third day after invasion the wound in the forearm was opened up and a fragment of shell the size of a small nut was extracted, the ulnar nerve having been injured. The dressing consisted of compresses soaked in the colloidal iodine preparation. Wellcome's antitetanic serum injected intraspinally, 30 c.c. on the day of admittance, 30 c.c. on the next day, 20 c.c. on the third day, 20 c.c. on the fourth day, and 30 c.c. on the seventh day; chloral; camphorated bromide oil. On the seventh day after admittance the heart became accelerated, the respiration obstructed, the temperature dropped below 38°, and death supervened from asphyxia and cardiac failure.

CASE 14.—Patient sent in by Dr. J— on Oct. 14th, 1914, in a condition of manifest tetanus. Wounded on Sept. 29th. Fragment of shell in the foot, having entered from the inner border; extracted from beneath the head of the fifth metatarsal. The fragment was irregular and of the size of a hazel-nut; at the same time shreds of manure were removed. Incubation period 6 days. Temperature raised, 39° to 40° C.; pulse 130. Very frequent and violent spasms; biting of the tongue; firm trismus; profuse sweating; uninterrupted asphyxial attacks. Treatment: Drainage by means of a compress soaked in colloidal iodine preparation, the end emerging from the orifice of the wound. 50 c.c. of French antitetanic serum injected intraspinally. The attacks continued to increase both in frequency and violence; the patient died on the following day from mechanical asphyxia, as much due to the thoracic muscles as to those of the glottis. Recently acquired experience teaches that one might perhaps have combated the asphyxia by tracheotomy.

CASE 15.—Patient of the tetanus section. Wounded on the banks of the Marne on Sept. 16th, 1914. Wound of the prepatellar serous bursa, containing shreds of clothing. Incubation period 11 days. Onset of tetanic symptoms about 4 P.M. on the 26th; mild trismus; mild opisthotonos; slight contractions of the muscles of the face and pharynx; muscular twitching. All these symptoms increased on the next day. Temperature about 37° C. Biting of the tongue; no profuse sweating; incontinence of urine during chloral narcosis. Treatment: On the day of onset, at 9.30 P.M., Dr. Doyen administered an intraspinal injection of 30 c.c. of French antitetanic serum, then 10 c.c. of English antitetanic serum after a few c.c. of cerebro-spinal fluid had been drawn off; on the third day 30 c.c. of French serum intraspinally, and on the fifth day 40 c.c. of French serum intraspinally; high doses of chloral. On the seventh day comatose condition, probably due to the chloral; involuntary micturition—this symptom disappeared on the drug being stopped. The recovery was slow, but could be regarded as complete at the end of 20 days.

CASE 16.—Patient sent in by Dr. B— on Oct. 12th, 1914, the diagnosis being tetanus. Wounded at Lihon on Sept. 25th. Wound due to fragment of shell which had remained in the right leg; fistulous wound of the thorax. Incubation period 17 days. Gradual onset. Temperature 37° C. on admission, 40° in the evening; it continued to oscillate between these two limits for four days, and then fell 1° during the next three days, remaining normal subsequently. Contractions; intense trismus and crises during the first three days; biting of the tongue; sweats. Treatment: Intraspinal injections of French antitetanic serum, 50 c.c. on the day of invasion after drawing off a few c.c. of cerebro-spinal fluid; on the third day 20 c.c. of the French serum after drawing off 20 c.c. of cerebro-spinal fluid; little chloral. From the third day onwards the condition improved, the crises diminished both in number and

intensity, and the trismus became less marked. On the fourth day the improvement was such that it was considered unnecessary to administer a fresh injection of serum. Recovery was confirmed after the eighth day, and was maintained at the end of two months.

CASE 17.—Patient of the tetanus section. Wounded on the banks of the Marne on Sept. 15th, 1914. Shell wound of the inner surface of the left leg; diffuse cellulitis; incised freely on admission. The temperature curve shows that the period of incubation may be gauged in two ways. This patient was operated on for a radical cure of hernia on the sixth day after admission. If Nicolaïer's bacillus had infected the wound on Sept. 15th the incubation period would have been 43 days at the most. If, on the other hand, the tetanus bacillus invaded the patient later, at the time of the operation, the period would have been 27 days at the most. The abscess in the scrotum, which supervened on the thirty-second day after the operation, is in favour of the second hypothesis. Onset extremely gradual; mild spasms of the mylo-hyoid producing a shagreen-like condition of the skin. Stereotyped sardonic expression of the mouth and eyes; very slight trismus; movements of the head caused the sterno-cleido-mastoid muscles to stand out under the skin. The temperature, having fallen to the normal level on the day after admission subsequent to the opening of the cellulitis, remained normal for 14 days. In the next few days it rose to 38.4° C., when the hernia operation was performed. It remained at about 38° with morning remissions for nine days and then fell for four days to from 36.8° to 37.2°. It then remained subnormal for nine days, and an injection of 10 c.c. of antitetanic serum having been administered on the following day, rose to 38.6° within 24 hours, dropping to normal on the day after, to rise again to 39.2° three days later when a scrotal abscess developed, and gradually sinking in four days to the normal level. The pulse varied in keeping with the temperature without being in any way peculiar. Biting of the tongue; no difficulty in swallowing or micturition; respiration stridulous on account of pharyngeal spasm. Treatment: Intraspinal injection of 10 c.c. of Wellcome's antitetanic serum. Recovery probably spontaneous.

CASE 18.—Patient of the tetanus section. Wounded on the banks of the Marne on Sept. 17th, 1914. Fistulous wounds in the right arm and thorax due to shell fragments. Incubation period 15 days. Slow but progressive onset. Temperature only slightly raised. The trismus became more and more marked from the first to the third day; no crises; biting of the tongue; no difficulty in swallowing; no respiratory discomfort. Treatment: Intraspinal injections of French antitetanic serum without preceding evacuation of cerebro-spinal fluid, 45 c.c. on the first day and 40 c.c. on the third. The first injection was followed by a severe general eruption of urticaria. No chloral or any other treatment. After the fourth day the symptoms rapidly subsided. Benign form. The question arises as to whether the serum was of any use whatever.

CASE 19.—Patient sent in by Dr. H.—on Nov. 2nd, 1914, in a condition of manifest tetanus. Wounded at Ypres on Oct. 25th. The tetanus was already manifest when the patient was received by Dr. H.—. General spasms had already been present for two days, the first having been felt on the evening of Oct. 30th. Bullet wound; wound of entry in the left buttock, that of exit on the inner surface of the thigh, 10 cm. from the fold of the buttock. Incubation period 5 days at the most. Temperature 36° C. on arrival, 39° after 24 hours, and 40° on the fourth day. Rapid, bad pulse. The state of intense and permanent contraction of all his muscular system might be described by the word "obstruction"; clonic spasms on the slightest excitation; biting of the tongue; profuse perspiration; the most alarming glottic spasms; urine and semen passed during the attacks; tracheotomy became necessary. The patient's intellectual power remained unimpaired to the last minute; though unable to speak, he succeeded in writing a few words, "I am thirsty," "Thanks." Treatment: Intraspinal injections of 50 c.c. of Wellcome's antitetanic serum on the first day, 20 c.c. on the next intravenously, 10 c.c. on the third day, and 10 c.c. on the fourth day. Chloral enemata; camphorated bromide oil. Tracheotomy performed on the third day; on the fourth day tracheo-bronchial obstruction,

copious mucous discharge, which was inadequately evacuated through the tracheal cannula, although the latter was of large calibre. Death simultaneously from asphyxia and circulatory failure.

CASE 20.—Patient of the tetanus section. Wounded on the banks of the Marne on Sept. 28th. Shell wound in the heel, slight. Incubation period 6 days. Sudden onset. Temperature (39° C.) higher before the appearance of tetanus than after. Very muscular man. Trismus; opisthotonos; very violent and frequent attacks of spasm threatening asphyxia; biting of the tongue; profuse sweating. Treatment: 50 c.c. of French antitetanic serum intraspinaly. Fulminating type; death on the fourth day. I tried in vain to open his jaws with a view to performing rhythmic traction on the tongue and artificial respiration. It was on this occasion that I made up my mind always to keep the materials necessary for tracheotomy in the special ward for tetanus patients.

CASE 21.—Patient sent in by Dr. V.—on Oct. 14th, 1914, in a condition of very acute tetanus. Wounded at Ypres on Oct. 8th. Shell wound in the lower part of the abdomen, entry in front of the left crural arch, exit above the pubis. Incubation period less than 7 days. Fulminating onset. Temperature between 39.5° and 40° C. Small, thready, rapid pulse; pendular rhythm of the heart; extreme rigidity of all the muscles. Treatment: In the department of Dr. V.—French antitetanic serum intramuscularly, about 12 hours before the diagnosis was confirmed; 15 c.c. in the lumbar region 12 hours later. In my special department 30 c.c. intraspinaly on Oct. 14th. Death in a state of muscular relaxation on the morning following his admission to the tetanus ward.

CASE 22.—Patient of the tetanus section. Wounded at Ypres on Oct. 22nd, 1914. Shrapnel wound in the thigh and left buttock of benign appearance. Incubation period 7 days. Slow progressive onset. Temperature 39° C. on the evening preceding the appearance of symptoms and 37° and 38° on the day itself. Pulse good on the first day; contractions and violent crises on the first day; firm trismus; biting of the tongue; profuse sweating; glottic spasm. Treatment: On the first day 30 c.c. of Wellcome's antitetanic serum were given, with chloral, by means of injections. On the afternoon of the second day the general condition was good, the eyes were mobile; there was little in the way of spasms and contractions. As the supply of serum had run low and the patient felt well, no fresh injections were made in order that the serum might be reserved for more serious cases. On the morning of the fifth day the condition became considerably aggravated; the trunk was in a condition of general contraction; the teeth were firmly set; the breathing was noisy and difficult. The condition had become grave. Towards midday the serum arrived. The patient was turned on his side in order to administer the intraspinal injection; three tubes of 10 c.c. each were injected; after this intervention extremely violent spasmodic crises supervened; the glottis closed; the patient was suffocating. He was rapidly removed to the operating theatre on the next floor below; a knife and forceps were found; asphyxia was almost complete, the patient had not breathed for nearly ten minutes; rapid tracheotomy; artificial respiration for five minutes. The breathing was re-established and the muscular system became less rigid. As no cannula was to be found we were forced to remove the inner cannula from a neighbour who had been tracheotomised the evening before—the one was left with the outer tube, the other with the inner. For two hours all went well, the cannula became obstructed, and the coagula were expelled forcibly. All at once the tube became completely blocked; it was removed, and the doctor was sent for at once, who hurried to the spot but arrived too late. Death from asphyxia due to the accidental obstruction of the cannula.

CASE 23.—Patient of the tetanus section. Wounded on the banks of the Marne on Sept. 16th, 1914. Wound from a rifle bullet on the posterior surface of the right thigh; general cellulitis of the whole limb. Incubation period 14 days. Insidious onset. Temperature oscillated about 40° C., might be attributed to the cellulitis. The pulse corresponded to temperature, 130 to 140. Risus sardonicus; trismus; difficulty in swallowing; spasmodic attacks; definite but mild signs of tetanus. Treatment: Intraventricular injections of 10 c.c. of the French antitetanic serum; chloral. The cellulitis was incised and drained six

days after the injury and eight days before the appearance of tetanus. After this intervention the temperature remained about 39° for four days. On Sept. 26th it suddenly rose to 39·8°, and on the next day to 40·4°. The patient manifested all the signs of septicæmia—drawn and leaden facies, rapid and bad pulse, dry tongue, diarrhoea. This condition was maintained subsequently, and it was only five days after the diagnosis of septicæmia had been made that the symptoms of tetanus appeared. The day following their appearance, 36 hours after the intraventricular injection of the serum, the patient died in a condition of muscular relaxation. This death should, it appears, be attributed, not to the tetanus, which was mild and in its early stages, but to the septicæmia.

Properly speaking, the following case ought not to be included in the series. The patient had arrived in *extremis*, emphysematous gangrene immediately recommenced in the stump, and one can hardly put down his death to tetanus.

CASE 24.—Patient of the tetanus section. Wounded in Belgium on Sept. 20th, 1914. He was left lying for three days on the battlefield before being picked up. Crushing of the femur in its upper third to the extent of about 10 cm. On the patient's arrival gas escaped from the cellulitic thigh; in addition there were painful cramps in the wounded limb. The diagnosis of tetanus was considered, but left undetermined. Incubation period not known, but in any case not less than 8 days. Temperature about 40° C.; pulse 140; profuse sweating. Emergency operation on his arrival, amputation below the trochanter. On the morning of the next day, Oct 1st, trismus. 10 c.c of the French antitetanic serum injected into each of the two cerebral ventricles. In the afternoon great restlessness; he beat his breast and expectorated a great deal; then he laughed, and joked in a delirious manner, asked to be allowed to get up; the trismus had diminished; garrulous; he recognised his relatives who had come to see him. Death on the same night.

Conclusions.

1. When one considers these cases as a whole the gross percentage figure of 58·8 survivors in cases of manifest and authenticated tetanus would seem to indicate that the treatment may have exerted some influence. The therapy employed was somewhat complex. Of the elements composing it, which, it may be asked, have been of utility? The measures employed were of two kinds. The object of the first was to prevent the onset of tetanus; as to this point one principle has emanated from the daily visiting of the patients. This precept is as follows:—

2. The treatment of tetanus demands that attention should be paid to all the factors; it must not follow some stereotyped formula, but should be gauged step by step according to the course of the symptoms. The treatment of tetanic attacks consists not only in employing opportune interference, but also, and perhaps above all, in not interfering unnecessarily, not touching the patient unnecessarily, not making him drink too frequently, not attempting to feed him at all costs—all these negative precautions are certainly of great value in contributing to his recovery. As to positive intervention, this should satisfy two indications: (a) to combat the fatal accidents connected with the respiratory system by performing tracheotomy, the instruments for which operation should always be ready to hand in the ward; and (b) to combat fatal accidents attributable to the cardiac system by means of camphorated oil administered in frequently repeated doses and by chloral in doses that should not be excessive. I have never exceeded 5 grm. per diem of chloral, but the drug may also occasionally have to be increased, and, on the other hand, it may have to be suppressed, according to the particular clinical exigencies of the case.

3. The results obtained were as follows:—

		No. of cases.	Re-covered.	Died.
Antitetanic serum.	Without colloidal iodine	10	4	6
	With colloidal iodine	14	10	4

We may subdivide the above recorded cases into two categories. Ten tetanus patients were treated by serotherapy without colloidal iodine treatment; of these, 4 recovered and 6 succumbed, giving a percentage of 40 recoveries. Fourteen patients were treated by serum therapy combined with colloidal iodine treatment; 10 recovered and 4 succumbed, a percentage of 68·8 recoveries. We are therefore justified in asking whether the association of colloidal iodine treatment with serotherapy may not possess a particular efficacy in the treatment of manifest tetanus. That this should be the case would, from a theoretical point of view, not be surprising when one bears in mind that the colloids tend to raise the opsonic index considerably as well as to increase the alexic power, and, on the other hand, that iodine, apart from its antiseptic properties, tends to induce active phagocytosis.

4. Colloidal iodine, whether it be administered in the form of intramuscular injections or be employed as a dressing for wounds, has never caused any local reaction, pain, or rise of temperature, and it is absolutely harmless. Numerous earlier experiments⁷ have demonstrated the microbicidal and antitoxic power of colloidal iodine on pneumococcus, staphylococcus, Eberth's bacillus, coli bacillus, and even Koch's tubercle bacillus.

5. As regards further research, we should study the following problems: (a) What is the rôle played by the antitetanic serum in the treatment and cure of manifest tetanus? Though possibly lacking true curative action—that is to say, being incapable of destroying the tetanus toxin that has once become fixed to certain elements of the nervous system—it may be that the serum, if administered in time, may still be capable of immunising those parts of the central nervous system, more especially of the medulla, which have not yet been attacked, in such a manner that the tetanus intoxication may at least become limited in its progressive course, although any fixation that has already taken place will persist. (b) What is the action of colloidal iodine on the antitetanic serum treatment? Does it act by enhancing the action of the latter? or by catalysis? or as an antitoxic agent? or, again, by stimulating phagocytosis? In any case we may mention that in the eight most satisfactory of our cases the quantities of serum that were injected were considerably reduced. Finally, what is the proper dose? All these questions await a definite answer.

⁷ Vide supra.

THE ASPIRIN TRADE MARK.—The Board of Trade has made an order regarding the aspirin trade marks, the effect of which is to make the word "aspirin" public property. As is well known this is the trade name under which the Bayer Company introduced acetylsalicylic acid and the name under which the drug is best known. It is now open to anyone to sell acetylsalicylic acid as aspirin, and it is hoped that this will not lead to any deterioration in the standard of the drug. As was mentioned in THE LANCET of Feb. 20th (p. 410) there are now several makers of acetylsalicylic acid in this country, and an examination of various samples has shown that chemically most of them are identical with the original aspirin.

ON HEADACHE ASSOCIATED WITH INTRANASAL DISORDERS.

By L. HEMINGTON PEGLER, M.D. EDIN., M.R.C.S. ENG.,
SENIOR SURGEON, METROPOLITAN EAR, NOSE, AND THROAT
HOSPITAL, FITZROY-SQUARE.

THERE is not any specific form or degree of headache in the common acceptance so far as I am aware that is characteristic of any one lesion in the upper respiratory passages, so that when we attach the designation "nasal" to headache we refer exclusively to the accredited organic source and not to any definite nature or location of the pain; but the term may pass, as it serves a useful purpose if we make proper allowances and do not attempt to force upon it a too rigid application.¹ A few examples will explain this. Some headaches are nasal indirectly rather than immediately, since though primarily arising from the source implied by the term, the resulting symptom may come about for the most part through the intervention of a changed condition of the blood, which reacts, we may suppose, upon the terminals of certain intracerebral peripheral nerves. More rarely we have evidence that a nasal headache is jointly produced, owing to the oculo-nasal distribution of the ophthalmic nerve, for it is found that a nasal defect can inhibit the best efforts of the refractonist to treat effectively an astigmatism or asthenopia until such defect has been disposed of, when relief comes to both the cephalic and ocular disturbance. Hence we cannot always draw a clear line between nasal and other headaches; indeed, there are numerous compound or mixed forms, the nasal stimulus, variable in degree, acting in consort with, e.g., a migrainous tendency, menstruation, or fatigue, which, singly or combined, manifest themselves by accentuating its effects.²

Etiology of Nasal Headache.

All evidence as to the etiology of nasal headache is derived from clinical experience. I am not aware of any investigations on other lines within recent years that have taught us a new fact. In every case we may assume a predisposition to this particular symptom because, although such proclivity to headache must be extremely common, it is difficult to explain otherwise the immunity enjoyed by people in whom one finds nasal conditions that would be highly productive of cephalic pain in the majority of mankind. There is much room for speculation as to the nature of this immunity, but I am confident there is no justification for stigmatising the opposite temperament as necessarily neurotic or neurasthenic.

Classification.

In attempting to classify the nasal causative agents commonly associated with headache, one finds it possible to arrange them into three groups, which placed in the order of their frequency and effectiveness are as follows: a simple or non-inflammatory, a chronic inflammatory, and a group in which inflammation or congestion is present more or less actively.

The utility of this arrangement is not greatly prejudiced by the fact that suppurative conditions may complicate the second and third groups, and

that a thickened or deflected septum may do the same. In the *first group*, headache is due to pressure somewhere within the nasal chambers of one more or less rigid body such as bone or cartilage against another, the richly innervated mucous membrane—often the cushion of the septum—intervening. This agent or force, whilst the most direct in operation, derives much importance through being often unapparent until a careful search by expert means has been made. A good instance is exemplified by a septal spine projecting against a middle or inferior turbinate, far back, and concealed by an anterior deflection of the triangular cartilage; such a condition may not be discoverable till after systematic packing of the nasal passages with gauze moistened in adrenalin and cocaine solution, or the adoption of some other mode of application of these agents, or even indeed until the anterior obstruction has been resected.

The *second or chronic inflammatory group* includes intranasal changes that imply contact between less resisting surfaces, the morbid effects of any resulting pressure being presumably subsidiary to others of superior energy, some further explanation being desirable to account fully for headache. Simple degeneration of the turbinal or septal mucous membrane entailing softening of bone in more advanced middle turbinal disease; polypi or polypoid degeneration, and possibly an allied condition affecting the walls or lining of one or more of the accessory sinuses, include the commoner types of pathological changes in this group.

The primary effects of the foregoing disorders are stagnation of secretions, hindrance to drainage and ventilation, and reabsorption into the system of muco-purulent or purulent material. If the fossæ are structurally narrow, or one alone is cramped by a deflection of the septum, the remoter systemic effects are all the more pronounced; these consist of circulatory disturbance such as lymphatic stasis, anæmia, or toxæmia enhanced by mal-oxygenation of the blood owing to abeyance of the nasal functions.³ Stasis in the cranio-nasal lymphatics, long accepted as a mechanical result of adenoid obstruction and one of the immediate causes of aprosexia, may be expected to arise out of these conditions, especially in young adults in whom adenoids are a frequent antecedent of the nasal morbid processes.⁴ Anæmia and toxæmia we know promote headache, but I have noted severe nervous breakdown from obvious purulent reabsorption with but little pain in subjects who are not predisposed that way. When, on the other hand, pus is imprisoned in some sinus or cell space, especially of the ethmoid labyrinth, headache is invariably severe and often accompanied by acute mental depression; re-establishment of drainage quickly relieves these symptoms even though suppuration continue.

The *third or inflammatory group* embodies those cases in which headache is associated with rhinitis, in its various forms, moist and dry, pain always tending to subside as congestion passes off. We see it typified in acute coryza, especially if it implicates the accessory cavities; sometimes also after nasal operations before reaction has subsided. Under obstructive conditions headache accompanies spasmodic rhinorrhœa, either perennial or seasonal (hay fever), and we have a common

¹ A paper by Harrison Allen (U.S.A.), On the Headaches which are associated with Chronic Nasal Catarrh, Medical News, March 13th, 1886, is the first known to the author upon this subject.

illustration in the aching discomfort, frontal and facial, of iodism; tumefaction having occluded the apertures of the accessory cavities their normal air is believed to be exhausted by absorption, and this engenders pain.⁵

The dry forms of rhinitis are also liable to occasion headache; the familiar rhinitis sicca with slight crusting, or strings of sticky secretion, has frequently an alcoholic basis, but pain is less common than in the foetid atrophic form, in which it is due either to the pressure or obstruction exerted by the foul inspissated masses which envelop the membranes. Some toxic absorption probably plays a part, but in all cases headache is diminished or kept at bay by free lavage. I have a patient suffering with this complaint in whom the local reaction after spraying the mucous membrane with adrenalin and cocaine will excite intense pain in the forehead accompanied by swelling and deep discolouration, pain radiating over the head and lasting four or five days.

The muco-perichondrium covering the sigmoid curves and angles formed by abnormalities of the septum, perhaps through intimate pressure, may independently set up headache, and if the projections impinge the opposite mucous surface at any point they usually establish adhesions. Synechia or adhesions are also sequelae of traumatic intranasal inflammation and granulations, and form fibrous bands of adventitious tissue across the fossae. In all these conditions headache is equally liable to occur, owing most probably to traction upon the nerve endings, as when they are destroyed I have always found that the pain is relieved.

Mechanism of Nasal Headache.

The mechanism of nasal headache can be best explained upon principles worked out for the rest of the body by Dr. Henry Head⁶ and Dr. James Mackenzie.⁷ The track of the nervous impulse is elucidated by a study of the fifth or trigeminal nerve and its connexions in some scheme or map such as I have already published,⁸ pain being mostly referred from a seat of excitation within the nose to a distant part of the head, either in the distribution of the same nerve or in that of the second or third cervical. Supposing the impulse to arise within the nasal fossae it is conceivable that the reference or projection will be either to the peripheral nerves of the scalp or to those of the dura. The weight of evidence seems to point at least in the case of pressure to the supra-orbital or occipital nerves of the scalp, yet in deep-seated nasal headache due to secondary circulatory disturbance there is no clear evidence that the dural branches are not involved. However this may be, admitting that the pain felt in a distant part somewhere in the distribution of the fifth, say the vertex, is referred from a nasal site of excitation, we may assume that an overflow of nervous impulse has taken place in some points or cell territories in the extensive sensory nucleus of the fifth nerve, situated in the pons and medulla, where other neurons from that distant part terminate. As a parallel example, if the sensation of pain is in the occipital region or back of the neck we assume that overflow has occurred lower down along the course of the descending

spinal root. A theory for neuralgia or neuralgiform pain rests upon the assumption that an impulse can pass from one afferent nerve to another when such nerves are closely bound up in the same sheath, as are the strands of the nasal nerve with those of the supra-orbital in the ophthalmic division of the fifth.

FIG. 1.

Diagram showing some parts of the trigeminal system concerned in headaches (dural filaments not represented). SO, Supra-orbital nerve. F, Frontal. N, Nasal. Oph, Ophthalmic. AS, Anterior septal. AT, Anterior turbinate. NPG, Naso-palatine ganglion. PS, Posterior septal. PT, Posterior turbinate. GG, Gasserian ganglion. P, Pons. M, Medulla. SN-Vth, Sensory nucleus of fifth nerve. DR-Vth, Descending root of fifth nerve. Gt Occ, Great occipital. C II, Second cervical.

The accompanying illustration (Fig. 1) will help the reader to understand the misreference of pain to distant parts of the head. With regard to the occipital region, it will be seen that the afferent fibres from the nose and sinuses may terminate through the descending root of the fifth nerve in the same mass of grey matter at the tip of the posterior horn and the substantia gelatinosa, in which also end the fibres that carry afferent impressions from the occiput and enter the spinal cord through the second and third cervical posterior roots. For this explanation of referred headache in the occipital region, which owing to its lucidity appears to me to strengthen on anatomical grounds the whole ingenious postulate of "misreference" of pain, I wish to express my indebtedness to Dr. Gordon M. Holmes.

I have lately been considering whether the extremely narrow "anterior nasal canal" through which the nasal nerve descends into the nasal fossa may not, under changed conditions of the nerve or its sheath, exert pressure calculated to set up a rhinalgia otherwise obscure as to its causation. Furthermore, an examination of sections shows that the bony canal itself is liable to be extremely narrow in calibre. I am indebted to Professor Thane for calling my attention to the ethmoidal aperture of this canal. (See Fig. 2.)

Diagnosis, Location, and Character of Nasal Headache.

It has been already indicated that the differential diagnosis of nasal headaches cannot be established by virtue of any characteristic feature. Their variation from the almost intolerable headaches of

⁸ L. H. Pegler: A Map Scheme of the Fifth Nerve, with Letterpress and Tables, Baillière, Tindall, and Cox, 1913.

the organic cerebral class is, I presume, one of degree or continuity rather than of localisation, but if the symptoms of sinus suppuration be included under the category of nasal headache, as is generally done, the circum-orbital pain of maxillary and post-orbital pain of sphenoidal and ethmoidal sinusitis may be regarded as of greater diagnostic value. The most frequent location of nasal headache is over the forehead below the hair line, when the patient in reply to inquiry instinctively draws a hand across the brow. Any line of extension is usually directly upwards to the vertex, less commonly it encircles the temple, least often the pain is referred to the occipital region and nape of the neck. From the earliest writings upon this subject to those of the present time, endeavours have been made to associate certain regions in the nose with definite areas for painful referred sensations in the head, but a glance through one's clinical notes shows that no data of statistical importance can be gleaned from them by which to establish genuine relationship. The mechanism of referred headache already given should make this fact intelligible. Many patients suffering from nasal disease seem to allow themselves to become in a sense inured to headache and, hopeless of relief, make little complaint until questioned on the subject.

FIG. 2.

A view taken vertically to the upper surface of the left half of the macerate cribriform plate (sagittal section, anterior extremity pointing to left). The nasal groove is seen half hidden running between the ethmoidal apertures of the anterior ethmoidal and anterior nasal canals. Partly concealed by the front extremity of the crista galli and separated by a slight ridge from the opening for exit of the nasal nerve is the nasal fissure or slit, stated in Gray's Anatomy, 1913, to admit a process of the dura mater. For further details consult the author's paper on the nomenclature of the nasal nerves in the XVth Section of the Transactions of the International Congress of Medicine, 1913.

Not rarely pains of different localisation and character in the head afflict a patient concomitantly; a highly intelligent lady, mistress in a county council school, whose case I have watched for some years, distinguished her headaches into three, distributed over separate areas though affecting her more or less synchronously. One of these, which she described as almost unbearable, was a neuralgic pain at the back of the head and seemingly behind the eyes; it often recurred during the day, kept her awake at night, and seriously affected her thinking capacity; it is worth remarking that while it continued, a patch of white hair conspicuously marked its situation. In addition to headache she suffered from asthenopia associated with a low degree of astigmatism; there were also chronic throat irritation and some nasal obstruction occasioned respectively by adenoids and hypertrophy of the inferior turbinates. These comparatively mild conditions proved nevertheless to be the key for the relief of the ocular disturbance as well as of the headaches, for neither expert refraction work nor prolonged rest from duty made any tangible impression till adenoid extirpation and partial resection of the turbinates had been performed.

In character and degree, a nasal headache may range widely between a continuous dull ache or occasional neuralgia, and a fulminating and throbbing seizure radiating pain to the teeth and along all the branches of the trigeminal nerve. In such an attack the scalp is hot and exquisitely tender—a condition persisting after the pain has abated—and there are often photophobia and alarming cardiac depression. I have met with this extreme form in cases where an incurved middle turbinate was pressing forcibly against the septum, and especially where other factors aggravated the initial trouble. Although when more than one cause is in operation such a headache is rightly to be regarded as a compound one,⁹ my experience is that if a proximate cause constituted by hard contact can be discovered and removed the attacks will not recur.

The complaint of a sense of tightness, if not of actual pain, at the root of the nose as the starting point of the headache often serves as a useful guide to the salient cause, and to the discovery of latent pressure or suppuration; sometimes, also, there are slight swelling and a bluish tint of the skin over the affected spot. If the lesion commences on one side, this disposition of the pain generally follows its extension towards the vertex; thus a unilateral character is given to the nasal headache, rendering it liable to be confused with true hemicrania or migraine. Absence of the classical signs of this complaint must be our guide in making a diagnosis, for if the patient can vouch for having experienced the fortification scotoma antecedent to the headache, admits a hereditary tendency, or has suffered from some other member of this symptom-complex, it is right to suspect that migraine is complicating the case. I have never yet seen genuine migraine in nasal disease as Grünwald¹⁰ and others say they have, though the semi-characteristic symptoms of certain neuroses, such as the circular band pain of neurasthenia and the clavus of hysteria, may at least be closely simulated in nasal cases. A neurotic patient, aged 21, referred to me by a distinguished neurologist, at whose hands she had undergone a course of medical treatment and who suffered from a peculiar pain compared to driving a nail into the vault of the skull (clavus hystericus), gradually became free after I had relieved the pressure exerted by a depressed and deflected septum against an inferior turbinate on the left side; the clavus was slightly lateralised correspondingly to the nasal lesion, a fact of diagnostic interest.

It is somewhat humiliating to have to admit, in face of so much positive evidence as to cause

FIG. 3.

Author's nasal probe and cottonwool-holder for investigating pressures or other conditions in the nasal cavities.

¹⁰ Grünwald: A Treatise on Nasal Suppuration, translated by Lamb, 1910.

and effect, that no intranasal appearance though strongly suspicious of setting up a painful excitation, and for all one can tell potentially pathogenic, can safely be regarded as *pathognomonic*. A fairly reliable prognosis may sometimes be arrived at by spraying the suspected area with cocaine and watching for temporary relief, or by a cautious insinuation of the author's nasal probe¹¹ (Fig. 3) into the olfactory cleft, but the sign may ostensibly portend much pain which is non-existent, just as in some other case the intensity of the pain may seem to us out of proportion to the objective sign. This brings one again to the impression that the essential foundation is a constitutional *predisposition*; this term is our main resource, failing a better, in the absence of definite knowledge regarding a human problem at present awaiting solution; but we are little better informed as to the underlying cause of susceptibility to the nasal neuroses, catarrhs, and asthma, often enough the accompaniments or alternatives of headache. Hence the confirmation of our diagnosis depends theoretically upon what has been called the "therapeutic test," and this works out well enough in practice; for, depending upon the matured judgment that comes of long experience, one rarely operates on a properly chosen case without success.

Treatment.

The treatment of these conditions is not necessarily surgical in all cases; if the pain of nasal headache is consequent upon obstruction due to catarrh or inflammatory swelling, reducible by simple but effective measures, it disappears *pari passu* with their application. When the original source is apparently in the nature of pressure there is generally a concurrent sensation of stuffiness in the higher recesses of one or both of the nasal cavities, if the middle turbinate is hypertrophied and cellular, or if the corresponding region of the septum is deflected or thickened, seeing that these abnormalities seriously hinder the free upward passage of the inspired air. In such case surgical treatment of the septum or turbinates can only do good, especially if Casali's view of causation here is correct (cerebral venous obstruction).¹² Intermittency of pain, so common in this class of case, may be attributed to the influence of the vaso-motor system on the nasal blood-vessels and spaces controlling the variations between tumefaction and comparative collapse of the mucous membrane.

The modern, and now perfected operation of sub-mucous resection of the septum is of great value in the treatment of irregularities of that structure that lead the way for headaches, and often facilitates a conservative treatment of the middle turbinates by rendering the septum negative as an opposing agent unless the former is very large or bulbous so as to press against the outer wall.

One may learn much from the study of cases in which a cure has been effected by operation performed at intervals according to the requirements of the situation. I have recently found it necessary to resect both middle turbinates a year after a previous operator had performed the submucous operation of the septum only partially relieving a severe neuralgic headache; the right turbinate had become cystic, but the opposite organ was

wing-shaped and had been flattened against the outer wall of the fossa by the septal deflection; the final effect was satisfactory. More recently I have successfully adopted a plan of gently forcing the flattened middle turbinate away from the outer wall and causing it to be retained there for a sufficient length of time by suitable means; this, of course, is not always feasible. In another patient it was necessary to reduce both inferior and middle turbinates successively at intervals during a period of three years before entire freedom from headache was attained. The result made it evident that each turbinate had by pressure contributed a part towards the elicitation of pain, and that this might therefore be termed a case of complex nasal headache.

So far I have desisted from resecting a middle turbinate in a doubtful case when I could perceive no actual contact with a neighbouring structure, but surprises sometimes await the rhinologist in this branch of his art. A distinguished *confrère* has related how he once fell into serious disfavour through declining to operate in response to a patient's reiterated request, his excuse being the very cogent reason that I have indicated. Following this persistent refusal another surgeon was prevailed to step in and resect the turbinate, after which the headache '*s'enfuit, et fuit encore*.'

Relief usually follows quickly upon the elimination of pressure unless the region is plugged after operating, when it may be slightly delayed. I have once or twice had an opportunity of noting the effect of a gauze dressing left by mischance in the olfactory cleft. The pain set up by this foreign body has not differed very materially from what is usually described when both opposing surfaces are nasal and vital. After clearing away the gauze the relief obtained is also essentially the same in all respects. I mention this fact because it seems to refute an opinion that has been expressed that turbinectomy in such an instance acts by producing an effect through the vaso-motor system and not by the removal of pressure upon the sensitive nerve terminals.¹³ The recovery of headache after surgical treatment may be somewhat tardy in some patients, in which case a short course of bromides or a few doses of phenacetin with caffeine are very helpful in accelerating the cure.

In conclusion, I should like to state once more that where there is the complication of an element of nasal disorder, with a dyspeptic, bilious, or other example of functional headache, the elimination of that nasal element should greatly ameliorate the severity of the general suffering, not only temporarily, as some assert, but permanently. In short, setting aside the purely cerebral organic headaches, and the numerous other forms which are beyond the scope of the rhinologist, there remains a large field of utility in this particular sphere which is always within his reach.

ROYAL DEVON AND EXETER HOSPITAL.—The 174th annual report of this institution, which has just been issued, states that during the past year 1926 in-patients were admitted, against 1680 in 1913, and this is the largest number of in-patients ever treated in one year at the hospital; the out-patients were 4248 compared with 3937 in the previous year. The ordinary income was £11,064 and the ordinary expenditure £12,479. The cost per occupied bed was £63 7s. 2d. per annum.

SECTION OF OTOTOLOGY.

Tuberculosis of the Auditory Apparatus.

THE meeting of this section held on Feb. 19th was devoted to a discussion on Tuberculosis of the Auditory Apparatus, Dr. ALBERT GRAY, the President, being in the chair.

Dr. WYATT WINGRAVE said that one of the first things sought for in examining ear discharge was the tubercle bacillus. In acute tuberculosis of the ear there was a reasonable chance of finding it, but it was almost hopeless to expect to in the chronic cases. He had only succeeded in his search in 16 per cent. of the chronic cases, while in the acute he was rewarded in over 50 per cent. In chronic discharges from the middle ear there was an acid-fast bacillus bearing a very close resemblance to that of tubercle, and it required careful analysis to differentiate, the bacillus of tubercle being alcohol-fast. In acute tuberculosis one found plenty of bacilli but very few giant cells, but in chronic cases this was reversed.

Mr. J. S. FRASER (Edinburgh) demonstrated a series of fine specimens of aural tuberculosis.

Mr. ARTHUR CHEATLE exhibited a series showing the continuity of tuberculosis of bone and membranes. He proceeded to discuss the question of human as against bovine tuberculosis, and related the case of a child, 7 weeks old, of wealthy parents, who had a discharge from the ear, which he (the speaker) regarded as tuberculous, although at the time there was no facial paralysis. An extensive operation proved to be necessary, and after a seaside residence the child recovered perfectly. The bacillus was proved to be of the typical bovine variety. He believed all the cases of the kind seen in children were bovine, and that infection took place through the Eustachian tube, milk being the infecting vehicle. He had never seen an adult with tuberculosis of the temporal bone secondary to lung tuberculosis in whom the disease ran the same course as it did in an infant; probably in the adult it was human tuberculosis and in the infant bovine.

Mr. C. E. WEST said that he had very rarely seen tuberculosis of the middle ear in either adults or children get well after extensive loss of membrane and secondary infection. He agreed that the typical course of the disease in the child differed from that in the adult; but of three recent cases of proven tuberculosis in children two were bovine and one human, the latter showing extensive destruction, with invasion of the labyrinth. The differing behaviour, therefore, he would ascribe to the character of the soil as well as of the seed. Owing to the habit of children putting their fingers into all kinds of places and orifices and then into their ears, the infection in them was usually very mixed. The majority of the adult cases he had seen had recovered if there had been no secondary infection or perforation, but he had never seen a chronically open tuberculous ear in an adult recover. The secondary infection with cocci, and especially with saprophytes, rendered the problem of disinfection of the ear almost insuperable. His chief hope for the future lay in the prospect of increasing immunity reaction, following upon bacteriological research.

Mr. E. D. DAVIS and Mr. W. STUART-LOW discussed the operative indications and technique.

Dr. LOGAN TURNER sent an interesting contribution stating that in eight years at Edinburgh Royal Infirmary there were 51 children under 15 years who had discharge from one or both ears of tuberculous nature. During the same period there were 1797 cases of middle-ear suppuration, of which 2 per cent. were tuberculous, 48, or 9 per cent., cases of middle-ear suppuration under 5 years were of the same character. In 43 of these 48 the discharge commenced before the first year of life had elapsed. During the eight years there were only 9 adult cases of tuberculosis of the ear, as compared with 51 in children. 88 per cent. of the affected children were bottle-fed, and in regard to some there was no record as to this. Facial paralysis occurred in 45 per cent. of the cases. Four of the patients died from tuberculous meningitis.

Sir ST. CLAIR THOMSON found but rare opportunities for the study of tuberculous disease of the ear in a large sanatorium; he had seen only 2 cases among 700 tuberculous patients, although 178 had tuberculous laryngitis. The two cases were painless and the discharge only slight. The few cases of the kind he had had, both in hospital and private practice, seemed to have been quite uninfluenced by sanatorium treatment.

Dr. DUNDAS GRANT found, on looking over numbers of cases, that there was only one case of suppuration of the middle ear to every ten of tuberculosis of the larynx, and he was sure that most of the suppurating cases were not tuberculous. He thought that in many cases of tuberculosis of the mastoid in children the infection was through the blood; but in the adult the infection appeared to be through the Eustachian tube, though this should not occur in health because the ciliary action tended to drive any infection towards the pharynx. But in wasting disease the patency of the Eustachian tube was increased. This had a very important bearing upon both prophylaxis and treatment. The main preventive in the child was care as to the purity of its milk food, while in the adult the condition of the nasopharynx should be watched. In some cases he recognised the disease owing to the presence of more than one perforation of the membrane.

Dr. W. JOBSON HORNE pointed out that bone had been found to be more susceptible to bovine than to human tuberculosis, and emphasised the large proportion of infants who were bottle-fed among the affected infants. He agreed as to the rarity of the involvement of the ear in patients suffering from general tuberculosis.

The discussion was continued by Mr. RICHARD LAKE and Mr. T. MARK HOVELL.

MEDICAL SOCIETY OF LONDON.

Continued Discussion on Radiography in its Relation to the War.

A MEETING of this society was held on Feb. 22nd, Sir JOHN BLAND-SUTTON, the President, being in the chair. The discussion, adjourned from Jan. 25th (reported in THE LANCET of Jan. 30th), was reopened by

Dr. A. C. JORDAN, who said that it might be inferred from recent discussions and articles that the precise localisation of bullets and other foreign bodies was of chief importance, whereas such localisation constituted but a small part of the uses of the radiographer in war surgery. He exhibited many radiograms which demonstrated the several points concerning which the radiographer could be of assistance to the surgeon, and an apparatus which provided a rapid method of precise localisation of foreign bodies by the fluorescent screen.

Dr. G. HARRISON ORTON demonstrated a method of localising foreign bodies embedded in the tissues. It was an adaptation of the triangulation method, and he had first used it several years ago. He thought that there was no difficulty for the operation to be done directly on the X ray table, a small sterilisable screen being employed. He exhibited several prints showing injuries to bone produced by rifle bullets.

Mr. S. GILBERT SCOTT spoke of the diagnosis of necrosed splinters of bone. Such sequestra, he said, were of two kinds, the one soft, poor in lime salts and consequently giving a faint shadow; the other hard, denser, with a heavier shadow. The detection of such splinters depended chiefly upon the surrounding shadow—i.e., upon whether the splinter was lying in normal bone, sclerosed bone, rarefied bone, in a suppurative focus, or in soft tissue, &c. The necrosed splinters could only be demonstrated if there was a sufficient contrast between their shadows and that of the tissue in which they lay. Rarefaction could often be seen in bone at some distance from the injury, but from its distribution did not appear to indicate merely atrophy from disuse. Mr. Scott also exhibited slides illustrating some curious effects on bones produced by modern projectiles.

Dr. STANLEY MELVILLE said that two questions were commonly referred to the radiologist. He was asked (1) whether a foreign body was present; and (2) as to its nature. He was also required to give its approximate anatomical relationships. Further details in localisation

were only occasionally wanted. The most careful localisation as to depth from the surface, &c., might be upset unless the surgeon had determined where he intended to make the incision before the localisation was attempted. He had come to rely more and more upon the help obtained from stereoscopic radiograms. He exhibited a special stereoscopic frame which had the advantage of easy portability.

Mr. E. W. H. SHENTON thought that much of the apparatus which had been devised had become too complicated. The use of a negative at the time of the operation together with a sterilisable graduated scale was a simple and often very effective method. He had devised a probe for the detection of foreign bodies which sterilised itself after introduction into the tissues.

The PRESIDENT said that it had occurred to him during the discussion that the radiologist was disposed to dictate whether a foreign body should or should not be removed. This was a position which could not be conceded by the surgeon. He had come to realise that all accessible foreign bodies which could be localised accurately should be removed. Clinical experience must always play a part in their localisation. The rarefaction of bone referred to by Mr. Scott was explained by sepsis.

Mr. V. W. LOW said that any one particular method could not be relied upon under all circumstances. For foreign bodies near the surface he thought that the exact methods giving their depths were very useful; but when the foreign body lay in the deeper parts it was more important to know its relation to anatomical structures than its exact distance from the surface. He agreed as to the value of stereoscopic methods under such circumstances.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Exhibition of Case.—Radium Therapy in Uterine Cancer.

A MEETING of this section was held on Feb. 5th, Dr. WALTER SMITH being in the chair.

Dr. T. P. C. KIRKPATRICK showed a boy suffering from a condition which was described as Lupus Pernio. The patient was affected for three years with sore hands, sore ears, and at one time had a similar affection of his face. The hands were said to be a great deal better now, but there was still much thickening, swelling, and ulceration. When first seen the condition of the hands was much more of the chilblain type, but the face had quite recovered except for some little scarring. He was treated with emollients, and the hands were kept wrapped up.—Dr. WALTER SMITH found fault with the nomenclature, and said the name lupus should only be used when the condition was tuberculous.

Sir JOHN W. MOORE related a case of a married woman, aged 65, admitted to the Meath Hospital in October, 1914, suffering from various symptoms attributable to the alimentary tract, as well as from uterine pain, discharge, and hæmorrhage. The condition of uterine cancer was recognised and pronounced inoperable by Dr. F. W. Kidd. In conjunction with Dr. W. C. Stevenson, Sir John Moore had the tumour treated with radium emanations from Oct. 23rd to Dec. 29th, an average of 20 millicuries being given for 13½ days. During all this time she had six old capillary tubes in a little metal case inserted into the cervical canal. They contained an average of 4.17 millicuries. She received altogether 6602 milligramme hours of radiation. Six needles were inserted 11 times, 24 each into the anterior and posterior lip of the cervix and fornix and 18 into the vaginal wall. Posterior fornix and lip of cervix, treated for 4 days 21 hours, received 1872 milligramme hours—average 16 millicuries. Anterior fornix and lip of cervix, treated for 6 days 12 hours, received 2162 milligramme hours—average 13.8 millicuries. Vagina, treated for 4 days 4 hours, received 1218 milligramme hours—average 8.1 millicuries. Cervical canal and uterus, treated for 13 days 6 hours, received 1350 milligramme hours—average 4.1 millicuries per hour. The constitutional febrile disturbance which followed the various séances was noteworthy. The patient left the hospital considering herself cured. There was certainly remarkable shrinking in the growth; the pain and hæmor-

rhage and foul discharge had ceased, and the patient's general condition was excellent.—Dr. C. M. O'BRIEN said the whole virtue of radium depended on the action of radium emanation on the cancer cells and also on the stimulation of the connective tissue cells. He recalled a case of his which was treated in 1906 for epithelioma of the right cheek, which was looked upon as cured and remained well for six years, and at the end of that time the patient returned with large infiltrating glands absolutely inoperable from the surgical standpoint.—Dr. W. M. CROFTON said that one would think that radium would produce a local effect only on the cancer, but it appeared that there was always a general reaction, and he suggested that part of this was due to the absorption of the cancer cell into the circulation, so that not only might the radium act as a destructor of the cancer cells, but it might lead to a certain amount of immunity.—Dr. W. G. HARVEY said Dr. Crofton's point should not be lost sight of. He found that when a tumour in a mouse disappeared after treatment with X rays it was almost impossible to reinfect that mouse with cancer. From that he considered that the absorption of the cancer did produce some kind of protective bodies.—Mr. SPENCER SHEILL said if it was assumed that the diagnosis was correct without microscopic examination, Sir John Moore was to be congratulated. If nothing more than the cessation of pain and apparent improvement had been achieved, that was still a distinct gain.—Dr. SMITH said the physics of radium was a complicated subject, and the question of its physiological action, which was of greater interest, was still more complicated. It seemed to him that the most fundamental thing in radio-activity was that it was a branch of phototherapy, and might be brought into line with Finsen light. He suggested that it was a photo-electrical treatment influenced largely by the wave-length of the light and possibly acting on the tissue. He suggested that in all those radio-active elements there might be a stimulant action; hence the possibility of too feeble an application of radium stimulating cancerous growths.

SECTION OF SURGERY.

Exhibition of Cases.—The Theory and Technique of a New Method of Radium Therapy.

A MEETING of this section was held on Jan. 29th, Mr. F. CONWAY DWYER, the President, being in the chair.

Mr. M. R. J. HAYES showed a man, aged 45 years, part of whose tongue was removed two years ago last June by Mr. S. S. Pringle for malignant disease. Mr. Pringle intended later to remove some enlarged glands in the neck, but the patient would not permit this. The tumour increased in size, and last autumn the patient came to the dispensary of the Mater Misericordiæ Hospital and it was decided to try radium emanations. When the patient was first treated by radium in the middle of December there was a swelling on the side of the neck about the size of a goose egg, soft about the centre, and apparently breaking down. Three needles were inserted from above downwards and three from below upwards and left in for 24 hours, when they were reinserted at right angles to the former positions. They were again inserted in a position which might have escaped radiation in the previous two insertions. There was no general reaction, but a slight local one. When the needles were withdrawn there was no hæmorrhage, and from that time the patient showed improvement. After Christmas the tumour was only half of its original size. Another insertion on Jan. 13th was tolerated for only a few hours. There is vast improvement. The primary growth was in the tongue. The submaxillary gland was at no time involved. The swelling now is only one-third of the original size.

Mr. R. C. B. MAUNSELL showed a man, aged 61, treated for Cancer of the Tongue by Radium Emanations. In April, 1913, the patient first noticed a lump under the tongue to the left of the frænum, which gradually increased, and ulcerated rapidly and spread. When first seen the man looked cachectic. There was ulceration of the left side of the middle third of the tongue, and a large ulcer under the tongue which destroyed the frænum. Considerable pain and enlarged glands on the left side but none on the right. A piece of the growth removed for examination, and reported on as a rapidly growing carcinoma. Radium was inserted Dec. 2nd. The position in which

the six needles were placed and the method adopted for fastening them were demonstrated. The only reaction was a rise in temperature to 100° F. Within a few hours the pain was relieved. The needles were left in for 23½ hours and inserted next day into the submaxillary gland, and the following day reinserted in the mouth. The treatment was then stopped awhile. On Dec. 24th the cancerous ulcer was completely covered with epithelium. The teeth were then extracted and 24 millicuries of radium again inserted, and the patient went home for three weeks. On his return he was in good spirits and greatly improved in general health. Since then the neck was radiated as a prophylactic. Glands were to be felt in the right side of the neck when he came back. An interesting point was that when a piece of the healed former cancerous growth was examined it was found to be covered over with practically normal epithelium, underneath which was a lot of fibrous tissue, and in one part of the section a mass of carcinomatous cells was to be seen, but there was no mitosis. There were a few giant cells. The point of interest was that although clinically the ulcer had healed over with epithelium there were still carcinomatous cells. Two sections were shown.

Mr. MAUNSELL also showed a patient suffering from Primary Cancer of the Neck under Radium Treatment, the interesting point being that the patient had a reaction each radiation, whereas the other patient shown had not.

Mr. WALTER C. STEVENSON brought forward four cases treated by Radium Emanation Needles. The first case was that of a man who had been shown two months previously. He had 13 radiations of six needles. The growth was considered to be a sarcoma. The opinion was expressed that sarcoma did better than carcinoma under radium treatment. The second and third cases affected the tonsils. The fourth patient had a tumour of considerable size on the face. He was X rayed about six years ago. Radium was tried, and the lump which was there had disappeared. The lump was considered to be an epithelioma following X ray treatment for lupus.

Mr. STEVENSON also read a paper on the Theory and Technique of a New Method of Radium Treatment by means of fine serum needles containing up to 5 millicuries of radium emanation in fine glass capillaries, as supplied by the Royal Dublin Society. He pointed out that the filtering off of soft rays, both in X ray and radium therapy, was simply a method of obtaining uniformity of radiation, as if the soft rays from an X ray tube or from radium, whether applied on the surface or buried in a tumour in the ordinary way, were not filtered off, there would be over-exposure and injury to the skin or tissues in the immediate neighbourhood of the source of radiation. By employing a number of sources of radiation, or illumination, as suggested by Professor Joly, in needles inserted within soft ray range of one another, uniformity of radiation was obtained with the minimum of filtering. The fineness of the needles permitted of their being withdrawn and reinserted in intermediate position for greater uniformity, allowed the growing edge of the tumour to be systematically dealt with, and, most important, increased the therapeutic value of a given quantity of radium, as the soft rays, which were the most numerous and therapeutically effective, were not wasted. It was not soft rays but over-exposure from soft rays that did the harm. Mr. Stevenson showed four patients and lantern slides of some other of the 22 cases of inoperable malignant disease treated since April 1st, 1914. He never was able to procure more than 24 millicuries of emanation at one time. The cases treated included malignant disease of the tonsil, tongue, and pharynx (3); floor of mouth, cervix and vagina (4); breast (2); glands in the neck (2); abdominal tumour. Six needles at a time were inserted into the tumour. All the cases in which this method was used proved that the treatment might be safely employed with marked benefit to the patients, some of whom were enabled to return to work.—The PRESIDENT said the paper opened up a subject which was only in its infancy, and every contribution to it was of great importance. He had no practical experience of the treatment.—Dr. O'BRIEN suggested the advisability of bringing the cases exhibited before the section from time to time in order that the success or otherwise of the treatment might be followed. The therapeutic use of radium entirely depended on its destructive power on cancer cells. There was no class of case more

discouraging as regards cure or treatment than those shown that evening. He thought the method described open to the objection that a cancerous growth being penetrated the patient might be exposed to the risk of the dissemination of cancer cells, though in a lesser degree than in any other method he knew of.—Professor E. J. McWEENEY said, as a member of the committee of the Royal Dublin Society, entrusted with procuring a supply of radium, he took a deep interest in the results, and by arrangement with Mr. Stevenson he had obtained specimens of the growths. Four or five of them were typical squamous epitheliomata, and others were sarcomata. There could be no doubt as to the malignancy of the growths; he considered that they would have caused the deaths of the patients speedily. He had not yet had an opportunity of examining them histologically after radium, but he had seen two microscopic sections cut from Mr. Maunsell's case, and they showed a most remarkable change. While further results must be awaited before passing judgment, the results showed clearly that a great amount of suffering had been alleviated by the treatment. The present contribution by Mr. Stevenson constituted a distinct advance in the surgical technique of the treatment of cancer carried out by these tubes with a small amount of emanation in each. He wished to acknowledge the great technical skill placed at their disposal by Mr. Moss, who devised the method of condensing the emanations at the temperature of liquid air and having it sealed up in these tubes in determined quantities.—Mr. HAYES said the instructions stipulating that the supply of radium emanations should be used for the particular patient for whom it was obtained, and not for any other case, caused a great amount of emanation to be lost, and he suggested that if the society could make some arrangement by which this waste of emanation could be utilised in other cases it would be an advantage. There was one matter which he considered they should be definite about. In X ray therapy dosage had been definitely settled, and it was just as well to realise that radium in ignorant hands was dangerous. He strongly urged the absolute necessity of fixing definitely what the dose should be in millicurie minutes. He doubted if there was any danger of dissemination of cancerous cells by the introduction of the needles into the growth, as the destruction in the tumour itself was relatively small; and, moreover, he believed that as a result of the immediate effect of the radium emanation occlusion of the lymph channels took place. He considered that there was not one of the cases shown that would not have died within a few months had they not undergone the treatment.—The paper was discussed also by Mr. W. I. DE C. WHEELER, Mr. MURPHY, Mr. MAUNSELL, and Mr. A. J. MCA. BLAYNEY, and Mr. STEVENSON replied.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—A quarterly meeting of this association was held at the rooms of the Medical Society of London on Feb. 18th, Dr. David G. Thomson, the President, being in the chair.—Mr. Roy M. Stewart (Prestwich Asylum) read a paper, illustrated by photomicrographs, on Meningo-Vascular Syphilis. It was devoted to the consideration of a single case, whose morbid anatomy afforded a striking example of the effects of the syphilitic virus on the supporting, enclosing, and vascular structure of the central nervous system; also to setting forth the retro-olivary syndrome dependent upon thrombosis of the posterior inferior cerebellar artery which the patient exhibited. As a brain might show both interstitial and parenchymatous change difficulties of diagnosis might arise, as there was no sign or symptom in dementia paralytica which could not be present in subacute meningo-vascular syphilis, and except for the Wassermann reaction one could not be certain whether a lesion was entirely parenchymatous. The patient who formed the subject of the communication was an unmarried woman, aged 47, who was in the asylum 17 months. She was anæmic and in poor physical condition. Near the right knee were scars of a syphilitic character. Her pupil reaction and reflexes were normal, but soon after admission there was ptosis on the left side. Mentally she was deluded and excited, believing that people were following her about to injure her. Speech was incoherent. During the

succeeding months there was progressive mental deterioration; she became restless, destructive, faulty in her habits, and was disorientated. Eleven months after admission she had a slight seizure affecting the left side of the face and right upper extremity, and subsequently a number of such; she also complained of failure of vision in the left eye. Speech was slurring and she had facial tremor. Three months before death she became bed-ridden and showed a powerful disturbance of memory. Two days before death she had a convulsion and symptoms of acute bulbar paralysis. She remained to the last conscious of her mental and physical disabilities. The whole picture was one of diffuse cerebral syphilis. At the necropsy the brain showed slight general atrophy. The pia-arachnoid was slightly thickened and milky along the frontal sulci, which were widened. There were gross macroscopic lesions and recent softening on both hemispheres. On making a horizontal section in Marie's plane several remarkable cavitations were seen in the white matter of $\frac{1}{2}$ cm. to 4 cm. in depth. The cerebral vessels were tortuous and very atheromatous. In the spinal cord there was a disappearance of many nerve fibres from all parts of the section. The lateral columns suffered especially, and there was a great increase in glial fibres. The myelinated sheaths showed every gradation of change, from slight loss of myelinated to complete disintegration. The pia mater investing the cord had undergone very great thickening and showed an intense cellular infiltration. Perivascular change was observed around all the large vessels, there was slight intimal proliferation in the arteries, and many of the veins showed engorgement and hyaline thrombosis. The nerve cells showed atrophic pigmentary degeneration. Mr. Stewart then gave a demonstration of the microscopical findings in the case, and remarked that, in regard to the optic nerves, a very large number of funiculi, especially those at the periphery, exhibited sclerosis. Their nerve fibres had largely disappeared and were no longer stained by Weigert's method. Large branching strands of neuroglia fibres could be seen passing among the nerve bundles. The symptom complex to which he wished to direct attention was as follows: Sudden onset, without loss of consciousness; giddiness, hemiataxia with tendency to fall to the affected side; difficulty in deglutition, phonation, and appreciation of pain, heat, and cold over part or the whole of the trigeminal area on the side of the lesion, and a corresponding loss of pain and temperature sense on the opposite side of the body from the face downwards; motor power, touch, tactile discrimination, deep pressure, and muscular sense were intact; paralysis of ocular sympathetic on the side of the lesion. It was clearly a case of crossed dissociated anaesthesia. He discussed the microscopic findings at length, and showed photographs.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—

A meeting of this society was held on Feb. 12th. Mr. Herbert Jones, the President, being in the chair.—Professor Sims Woodhead read a paper on the Best Way in which Civil Health Officers can give Assistance to the Military Authorities in Time of Mobilisation or of War, and said that the Local Government Board, knowing the value of the experience of medical officers of health, early recognised that their help might be of enormous value to the military authorities, and soon after the outbreak of war sent out a series of circulars to both sanitary bodies, civil and military, inviting the confidence of one and placing the services of the other at the disposal of the military authorities. The chief features essential for the smooth working of the civil and military authorities side by side were a free interchange of information and ideas, which could only be effected where there was a readiness to help; avoidance of bones of contention, which could only be done by a willingness to delimit spheres of observation as far as possible and by accepting without cavil or mistrust slight invasions of those spheres; subjection of official interests to the general convenience; and mutual trust and forbearance. The medical officer of health could exert little or no control over meat supplies or food supplies of any kind. The inspection of rations must be left entirely to the company officers and to the Royal Army Medical Corps Sanitary Service. The military authorities, although nominally applying to the police for information concerning open spaces in which camps might be erected, were to a very large extent dependent upon information that could only be supplied to them by the

medical officer of health. He could keep them posted as to the places to be avoided. He had a knowledge of the character of the population, of the localities in which undesirables of both sexes were concentrated, the type and efficiency of the sewage and drainage of an area, the character of the soil, and the facilities for obtaining water and for the disposal of camp refuse. The military authorities must be entirely dependent upon the medical officer of health for information that was vital to the success of their efforts to keep the troops healthy, and they must rely upon him for accommodation of their fever patients in his isolation hospital. Referring to cerebrospinal meningitis, he expressed the opinion that the disease was associated essentially with overcrowding and bad ventilation, and that the latter rather than the former was the determining factor; that it was no longer a jail fever, in civilised countries at any rate, as jails were now as well ventilated as dwelling houses; and that it was a disease of the barracks and not of the open camp, though when weather was bad and tents good the conditions for its development even under canvas were not wanting. An outbreak of the disease would be got rid of by thorough ventilation of the military huts. This was of far greater importance than isolation.—Dr. J. S. Tew said that he was able to supply the military authorities on the outbreak of war with a complete plan of all the water mains in his districts and to indicate the locality of wells. He referred to the importance of cheap bathing facilities for soldiers and of adequate means of disinfection.—Dr. Veitch Clark said that in Croydon an enormous amount of disinfecting had been done by the corporation free of charge, and that some public baths had been given up entirely to the soldiers on payment by the military authorities of a weekly sum equal to the average takings. He considered that much good had been done by making out of bounds certain streets in which infectious diseases were prevalent.—Dr. A. W. J. MacFadden referred to the excellent work that was being done by medical officers of health, at the instance of the Local Government Board, in the examination of the food-supplies of the army. He knew that the War Office was aware of the services of medical officers of health in this direction.—Mr. T. W. N. Barlow regretted that the military authorities did not always seek to coöperate with the medical officer of health, whose advice was not invariably followed.—Dr. R. A. Lyster, Dr. A. H. Bygott, Dr. C. Sanders, and the President also took part in the discussion.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held in the Metropolitan Hospital on Feb. 19th, Dr. David Ross, a past President, being in the chair.—Dr. Philip Hamill conducted a clinical demonstration.—Dr. Edmund Cautley showed: 1. A girl, aged 15 years, who though looking well and having no pains or fever, had a Diastolic Murmur at the Base of the Heart conducted to the right side of the sternum. The point of maximum intensity was in the second and third left interspaces. A skiagraph showed hypertrophy of the right ventricle.—A discussion followed, in which Dr. Leonard Williams, Dr. Hamill, Dr. A. Feiling, and Dr. H. E. Symes-Thompson joined, and it was ultimately agreed that the case was one of pulmonary regurgitation. 2. A boy, aged 9 years, with Subaortic Stenosis.—Dr. Hamill showed (for Mr. Dive and on his own account): 1. A boy, aged 8 years, with Pulmonary Stenosis. 2. A man, aged 28 years, with Pulmonary Stenosis and Tricuspid Regurgitation. 3. A girl, aged 9 years, with Pulmonary Stenosis and Patent Ductus Arteriosus with marked Cyanosis. 4. A girl, aged 11 years, with Patent Ductus Arteriosus, who suffers from epileptiform seizures. 5. A girl, aged 18 years, with Pulmonary Stenosis and Patent Foramen Ovale (? Defective Ventricular Septum), marked Cyanosis, and Clubbed Fingers. 6. A girl, aged 12 years, with Complete Transposition of Viscera. 7. A man, aged 20 years, with Transposition of Heart only, Stenosis of Ostium, and probably a Defective Auricular Septum. 8. A man, aged 34 years, with Heart drawn over to the right side by Fibrosed Right Lung. 9. A youth, aged 15 years, with Mitral Stenosis and marked Clubbing of the Fingers. 10. A woman, aged 30 years, with Chronic Inflammation of Both Submaxillary Ducts who spontaneously passed a salivary calculus.—Mr. Henry Curtis showed a specimen removed from a case of Multiple Urethral Fistula, one in the right groin and three in the perineum, in a West Indian Negro.

Reviews and Notices of Books.

The Extra Pharmacopœia of Martindale and Westcott.

Revised by W. HARRISON MARTINDALE, Ph.D., F.C.S., and W. WYNN WESTCOTT, M.B. Lond., D.P.H. Sixteenth edition. In two volumes. London: H. K. Lewis. 1915. Vol. I., pp. xl. + 1113, price 14s. net; Vol. II., pp. viii. + 469, price 7s. net.

SINCE the publication of the last edition barely three years ago a very considerable amount of attention has been directed to different topics which are dealt with in these volumes. The revision has entailed drastic excision of many details to make room for more recent information and for somewhat lengthy reports of many matters connected with proprietary medicines. The first volume is that which will be most frequently consulted by medical men, and it certainly succeeds in supplying concise accounts of current expressions of opinion on the trend of therapeutics. The second volume is intended as a supplement for further study, and deals mainly with the results of analytical or experimental investigations. The references to the new British Pharmacopœia are necessarily very numerous, though the compilers save much space by frequently indicating, by the abbreviation "Off." the advisability of looking elsewhere for further information regarding official requirements. The remarks on the metric system in the present edition will come as a surprise to those who remember the whole-hearted recommendations of former editions, in which it was advocated as entailing far less mental calculation and therefore very much less likelihood of error. It appears a little inconsistent to advocate uniformity in nomenclature at the top of the page, and a little lower down to state that though the word "mil" is now adopted officially, the use of "cubic centimetre" with the contraction cc. is retained throughout these volumes.

Among the more important new features we find, alphabetically arranged in the preface, brief references to all that is newest in the domain of therapeutics, together with a few useful indications of the lack of satisfaction expressed about some measures which, until recently, had met with wide acceptance. These pages are extremely instructive, although they often suggest the idea that many of the vaunted remedies of recent introduction may have an ephemeral existence. It is evident, however, that the compilers of the Extra Pharmacopœia are fully alive to this, and that, not content with merely making an abstract of current literature, they initiate independent investigations to test the validity of the claims made on behalf of new remedies, and have not hesitated to add to the list of new aspirants for favour. For example, having found certain objections to cod-liver oil, they suggest the use of poppy-seed oil as a suitable substitute, and quote clinical observations in its favour. Many busy men will be grateful for the amount of space devoted to radiology, to radium, and to radioactive waters, since it is difficult elsewhere to find so much information in so compact a form. The same remark is equally applicable to the sections on vaccines, on tuberculin treatment, and on organotherapy.

In the second volume there is greater scope for dealing critically with the new British Pharmacopœia, and although some strong remarks are

made about the absence of a standard for dried thyroid gland, it is evident that most of the official analytical processes and methods of extraction meet with approval. It is somewhat difficult to criticise this volume owing to the multiplicity of subjects included and to the strange order in which they are placed. Each section, viewed by itself, affords a vast amount of instructive and suggestive information, but the sections succeed each other with a bewildering lack of connexion, and occasionally some seem to have strayed from their proper logical position. Thus in rapid succession we pass from animal organotherapy to sterilisation, then to synthetic notes on physiological effect in comparison with chemical constitution; from this to physiological standardisation, and then to proprietary medicines and their approximate composition. The last-named section gives a very fair précis of some of the evidence taken by the Select Committee appointed to inquire into the conditions prevailing in the United Kingdom regarding the sale of patent and proprietary medicines, to which is appended a list of proprietary medicines, with a moderate amount of information of their composition, culled from various sources. From this list it is evident that the composition of some has been altered from time to time; it is also clear that no information is forthcoming with regard to certain largely advertised proprietary preparations. The authors remark that the various scientific journals do not give a complete report of all the evidence given before the Select Committee, and they have clearly done their best to make good the deficiencies. The notes on the antiseptic power of numerous chemical and disinfectant preparations have been very carefully revised, and include records of the results obtained by numerous independent observers. Many of the experiments have been conducted by one of the authors, and in tabular form the germicidal action of those of practical value is clearly set forth. The analytical memoranda relating to the examination of urine, blood, fæces, &c., have been brought up to date by the inclusion of many new tests and by useful summaries of recent discussions, while the bacteriological notes supply considerable detail which will be sure to be frequently referred to by those engaged in this branch of special laboratory work.

Sufficient has been said to warrant the conclusion that this new edition is likely to receive the same welcome afforded to its forerunners. Notwithstanding the vast amount of information afforded, the clearness of the type and the use of thin paper have enabled the production of two volumes of convenient size and agreeable appearance. Those engaged on the revision are to be congratulated on having produced a work of great utility.

Mentally Defective Children.

By ALFRED BINET and TH. SIMON. Authorised translation by W. B. DRUMMOND, M.B., F.R.C.P. Edin. London: Edward Arnold. 1914. Pp. 179. Price 2s. 6d. net.

WE are glad to welcome this useful translation of the work of M. Binet and M. Simon. The care and education of the feeble-minded have in recent years been brought much to the fore as a matter of pedagogical, social, and medical interest. Volumes have been written, an immense amount of work has been accomplished, and a few results have been attained. So great has been the enthusiasm in certain quarters that there has seemed almost a

danger of the child being lost sight of in the multitude of tests and other psychological experiments to which it might appear he was about to be subjected.

The great merit of Binet and Simon's book has always seemed to us that it has focused the attention of those who have to do with the education of the feeble-minded upon practical inquiries as to when a child is to be considered feeble-minded, to what extent it may be expected that good results will arise from education, and in which cases a large outlay of patience, money, and time is justifiable. The Binet-Simon tests have now a world-wide reputation, which they have merited on account of their simplicity, practicability, and usefulness. Their use will, we scarcely doubt, be widespread, and upon them will be based a classification of the feeble-minded which, from the pedagogical point of view, will be of great value.

The translation has, we consider, been particularly well done, and while the English is excellent the style retains the incisive nervous qualities of the original French.

Infection and Resistance: An Exposition of the Biological Phenomena Underlying the Occurrence of Infection and the Recovery of the Body from Infectious Disease.

By HANS ZINSSER, M.D., Professor of Bacteriology at the College of Physicians and Surgeons, Columbia University, &c. With a chapter on Colloids and Colloidal Reactions by Professor STEWART W. YOUNG, Department of Chemistry, Stanford University. New York: The Macmillan Company. 1914. Pp. 546. Price 15s. net.

So many books dealing with the subject of immunity have recently seen the light that we are inclined to view any newcomer in this field with suspicion, but the present volume has quite definite merits of its own. It gives a clear account of the phenomena of immunity, written largely from the historical point of view, enabling the reader to follow to some extent the gradual development of knowledge. He is thus led to take an intelligent interest in the subject, and to appreciate the fact that accepted doctrines at this, as at earlier periods are provisional and subject to continuous modification with the growth of experience. References are given to the original papers quoted, a feature which adds considerably to the value of the book.

With regard to the plan of the book, the first chapter deals with the virulence of organisms, and the second with the nature of bacterial poisons. Chapters III. and IV. treat of the forms and mechanism of immunity, and Chapter V. of the relations of toxin and antitoxin. In Chapter VI. we are introduced to the phenomena of bacteriolysis and cytolysis, and the two following chapters deal with complement and its fixation. Chapters IX. and X. are devoted to agglutination and precipitation respectively, while the following four discuss phagocytosis and its relations to vaccine therapeutics and to opsonic determinations. Chapters XV. to XVIII. are devoted to anaphylaxis and the clinical conditions connected with it, while Chapter XIX. deals at some length with serum treatment and prophylactic inoculation. Some account is given in Chapter XX. of Abderhalden's protective ferments, and the concluding chapter contains Professor Young's epitome of our existing knowledge of the properties of colloids—a subject intimately connected with the reactions concerned in immunity.

We could indeed have wished that this last chapter had been even longer and fuller, but for its presence at all we may be duly thankful.

The volume is intended for the use of students of medicine, and we hope it will find many readers among them, as in the form here adopted it affords better mental pabulum than more dogmatic text-books and other forms of pre-digested matter which are too commonly relied upon in these times of continual examinations and general educational haste.

Food Products.

By HENRY C. SHERMAN, Ph.D., Professor of Food Chemistry, Columbia University. New York: The Macmillan Company. 1914. Pp. 594. Price 10s. net.

THIS is a useful book giving considerable information upon the production and preparation of food and food products. Indications are given as to the relative economic importance of the industries concerned, and a valuable feature of the book appears in a section on the special characteristics of composition, digestibility, nutritive value, and place in the diet of all known foods. The analyses given are abundant, and form a useful reference. The literature quoted is extensive.

The sections on the administrative control of food supplies are of course based on the provisions of the laws of the United States. This does not detract from the value of the author's treatment of general considerations or from his account of industrial methods.

The Sale of Food and Drugs Acts, 1875 to 1907, and Forms, Regulations, Orders, and Notices Issued thereunder, with Notes and Cases.

By the late Sir WILLIAM J. BELL, LL.D., Barrister-at-Law. Sixth edition, by CHARLES F. LLOYD, Barrister-at-Law; the Chemical Notes revised and enlarged by R. A. ROBINSON, Barrister-at-Law. London: Butterworth and Co. and Shaw and Sons. 1914. Pp. xxxix. + 310 + 46. Price 8s. 6d. net.

LET us say at once that Mr. Robinson's useful notes upon the points likely to arise and to be submitted to the analyst in connexion with prosecutions for adulteration have been added to with advantage and placed in a more convenient position in this edition than in its predecessor. The present volume constitutes the sixth issue of "Bell's Sale of Food and Drugs Acts," and for the first time the original editor's name is prefixed with the words "the late." Mr. Lloyd and Mr. Robinson were already responsible, however, for the fifth edition issued in 1910. Not a great deal of legislation has occurred since that date to swell the bulk of the present volume, and Mr. Lloyd is to be congratulated upon having been able to keep its dimensions in check by omissions of practically obsolete matter which is not likely to be missed. The only serious legislative addition which he has had to insert is the Milk and Dairies Act, 1914, and in making reference to other new statutes he has only chronicled a doubt as to who is to be deemed the purchaser of drugs under the National Insurance Act, the committee or the patient, and noted the effect of the Forgery Act, 1912, upon proceedings in respect of forged certificates and warranties, where these have hitherto been regulated by Section 27 of the Food and Drugs Act, 1875. Otherwise recent cases and decisions have afforded the principal matter for editorial consideration.

We may note that the ingenuity of the inventor has found scope since the last edition in the adulteration of margarine with paraffin. Observations upon this subject are to be found in a memorandum of the Local Government Board, a number of circular letters from Government departments having been included in the appendix to the present issue. These, together with forms of information and summons, should be found convenient additions to a volume which for some time has been recognised as a useful text-book.

LIBRARY TABLE.

The Passing of Vesalius. By G. MATHESON CULLEN, M.D., B.Sc. Edin. Reprinted from the *Edinburgh Medical Journal*, November, 1914.—Dr. Cullen, in his small monograph on "The Passing of Vesalius," has made a minute examination of the original sources of information, and has endeavoured in the true historical spirit and method to appraise impartially the value to be assigned to each authority. The most important of these, because that upon which the prevailing view is based, is a letter alleged to have been written in 1565, the year following the death of Vesalius, by Languetus to his friend Casper Peucer, physician and son-in-law to Melancthon, wherein the story is found that the Spanish Inquisition satisfied its enmity against Vesalius by a charge of impiety, for his (alleged) opening of the body of a Spanish nobleman to ascertain the cause of death, when the heart was found to be still beating. For this, it is stated, the Inquisition determined to sentence him to death, but at the entreaty of the king changed the sentence to an expiatory pilgrimage to Palestine and Mount Sinai. Nothing appears to have been known of the version contained in this letter, however, until Melchior Adam published it in 1620, in his *Vite Germanorum Medicorum*. Even then it failed of credence until Boerhaave and Albinus accepted and republished it in 1725, when it became more or less generally adopted. But Languetus speaks of it only as a tale he had heard from Spain, without even referring to his authority. Beyond a vague statement by Paré there appears no other evidence in support of the alleged "vivisection." As to the interference of the Inquisition Languetus stands alone, and in view of the prevalent animosity against that body, it seems incredible, as Dr. Cullen points out, that had the charge been true it should not have gained currency in the copious polemical literature of the time, for several of Vesalius's friends were of the anti-Spanish and Protestant party; his widow's brother-in-law by her subsequent remarriage was a partisan of William of Orange; Languetus himself was the accredited agent of Augustus Elector of Saxony; the friends of the nobleman in question remained silent on the subject; and lastly, in spite of the Inquisition's well-known punctiliousness in recording minutes of their judicial proceedings, there is no trace to be found of any official record concerning it. Dr. Cullen seems, therefore, to be quite within the bounds of probability in concluding that the story is a forgery fathered on Languetus.

Other reasons that have been assigned for the pilgrimage are a wager (Metellus, 1565), the enmity of the Galenists (Argentarius), a vow for recovery from sickness (Clusius, 1564, Solenander, 1566, but not printed until 1722, Dudith, 1582, who explicitly denies that Vesalius was exiled), and a

desire to visit the holy places on a pilgrimage from religious motives (Pantaleon, 1565, Zuinger, 1586, Thuanus, "for his soul's sake," 1606, Miræus, 1609, Melchior Adam, 1620, and Sweetius, 1628). Dr. Cullen passes all these authorities under careful review, and, as it seems to us, makes out a good case for the conclusion that there is no reason to suppose that Vesalius was other than a sincere Christian believer, and that the reason he left Spain was "that in consequence of a vow he was anxious to obtain the merit of making a pilgrimage to the places which had been hallowed by the living presence of our Saviour."

Vade Mecum for the Use of Officers and Interpreters in the Present Campaign. By EUGENE PLUMON. New edition. London and Paris: Hachette et Cie. 1914. Pp. 134. Price 2 francs.—This is a manual that can be easily carried in a breast pocket, and within the limits that the author has chosen contains all the technical terms likely to be required in intercommunication between our troops and their Allies, as well as ordinary useful words, arranged according to subjects. It is not a conversation manual, but a classified vocabulary of military, topographical, and engineering terms and expressions. The definition of military terms is not always quite accurate: "accoutrements" do not include "arms," which are certainly part of "a soldier's outfit"; the definition of "echelon," as given, is incomplete and erroneous; that of "interval" substitutes "of" for "or," which makes it meaningless. There is, however, a very useful selection of words in the two languages, which makes the book useful and handy.

The Practitioner's Guide to Clinical Research: Alphabetically arranged in Sections. Published by the Clinical Research Association, Limited, Watergate House, York Buildings, Adelphi, London, W.C. Pp. 149 + xlix.—This little book is doubtless primarily intended for the use of members of the Clinical Research Association, containing as it does advice on the subjects suitable for laboratory assistance and the scale of fees payable for such aid. Nevertheless, it is also of interest to the general reader as showing at a glance the present state of knowledge in the field of applied pathology—a field which has grown enormously in recent years and is constantly extending. As examples of such recent extension we may note the complement-fixation tests for glanders and for hydatid disease here described. The methods of collecting blood and other materials for examination are also explained—a further useful feature.

The Mental Health of the School Child. By J. E. WALLACE WALLIN. London: Humphrey Milford. Oxford University Press. New Haven: Yale University Press. 1914. Pp. 462. Price 8s. 6d. net.—This book consists of a collection of papers and addresses written to advocate the support and foundation of "psycho-educational clinics" and as contributions to a "new science of orthophrenics and orthosomatics." Orthosomatics or physical orthogenesis is defined by the author as "any process through which malfunctioning physical organs may be made to function aright, or by means of which healthy organs may be continued at normal functioning so that the physical organism may develop to its maximal potential," and orthophrenics or mental orthogenesis as "any process, mental or physical, of righting any malfunctioning mental power so that the mind may reach its highest developmental

possibilities." The enrichment of our vocabulary proceeds apace, and those who regard the invention of a new term as an advance in knowledge will welcome these additions. The new problems presented by orthosomatics and orthophrenics are to be the subject-matter of "clinical psychology," the claims of which to recognition as an independent science are supported at length by the author. "The central aim of the psychological clinic is psychological diagnosis and consultation and advice in regard to mental cases, particularly children." The author occupies considerable space in support of theses such as these. His style is unfortunately somewhat diffuse, and this quality is accentuated by the repetition which he regards as unavoidable in the publication of a series of scattered studies dealing with closely related topics.

The B.D.H. Guide to the British Pharmacopœia, 1914. London: The British Drug Houses, Limited. 1915. Pp. 175. Price 1s. net.—This is a very pleasant book, of convenient size, well printed, and clearly arranged. It is intended to save the time of those who might wish to compare the B.P., 1914, with that of 1898. Each monograph is mentioned in turn, and when changes of importance occur the fact is noted, the degree of importance being indicated by a single or double marginal line. Greater courage is displayed than in the parent volume, to which it is a guide, for the mystery surrounding new articles like barbitone and hexamine is dispelled, and we are plainly told that they have the same chemical composition as certain proprietary substances. The general commentary at the beginning of the book deserves careful study, otherwise the value of many brief statements may be missed; for example, the difference between "no change" and "no ostensible alteration." Although the compilers of this book show due regard for accuracy in all relating to the new Pharmacopœia, they are in error in stating that in 1898 æther was required to be prepared from *duty-paid* rectified spirit.

New Inventions.

VACCINE BOTTLES FOR HYPODERMIC SOLUTIONS.

It is needless for me to claim any originality except for the application of Sir Almroth Wright's vaccine bottles for hypodermic medication. On the battlefield in particular, where morphia is the sheet anchor of the first-aid surgeon, such an arrangement of keeping the morphia solution would be a great advantage over the glass capsules or the compressed drugs.

In order to ensure as great a sterility in hypodermic medication as possible glass capsules, each containing single doses of a particular preparation, have been put on the market in place of the compressed drug. In practice the disadvantages attending these devices are: (1) The space the capsules occupy; (2) the fragility of the containers; (3) chances of accidental contamination in filing the capsule and breaking the neck thereof; (4) assistance required in holding the capsule while drawing the contents into the syringe; (5) the difficulty of obtaining the capsules in India (except in Presidency towns); and (6) the cost, especially in the treatment of malaria and in hospital practice, and even in general practice. To obviate these difficulties I am now using Sir Almroth Wright's rubber-capped vaccine bottles. In two months I used more than 100 doses from the vaccine bottles without having a single accident.

The method of preparing the solutions for hypodermic medication and putting them in the bottle, &c., is as follows: 1. Make the solution of the required alkaloidal salt in

distilled water (e.g., 3 gr. of quinine bihydrochloride to 1 c.c. or even $\frac{1}{2}$ c.c.) and filter. 2. Charge a thoroughly cleaned and sterilised vaccine bottle with the solution (1). Cap the bottle with a thick rubber cap. 3. Thrust a small section of hollow wire or a fine hypodermic needle through the cap near the edge to serve as an air vent. 4. Sterilise the bottle and contents in an autoclave. 5. After sterilisation and cooling pull out the wire or the needle and seal the hole with collodion. 6. Melt some hard paraffin and let it boil; then dip the rubber-capped neck of the bottle into the melted paraffin. This would prevent any possible leakage about the neck or top and also be a protective layer for the rubber cap (a great desideratum in the tropics).

The method of use is to sterilise the surface of the rubber cap by transferring to its surface a drop of undiluted lysol and then, turning the bottom of the bottle upwards, puncture through the rubber with the needle of a sterilised hypodermic syringe and withdraw the desired quantity of the solution. The hole seals itself and no collodion or re-paraffining is necessary, which is one of the advantages of such a cap.

S. N. GORÉ, L.M. & S. (Bombay Univ.),
First Assistant to the Chemical Examiner and Bacteriologist,
United Provinces; and Lecturer on Chemistry and
Physics, Agra Medical School.

INFLUENZA IN BELFAST.—Our local correspondent states that there is a very widespread epidemic of influenza in Belfast at present, the main feature of which is the severe throat complications—acute follicular tonsillitis and laryngitis—and occasional gastric symptoms. Young people seem to be very susceptible.

ROYAL METEOROLOGICAL SOCIETY.—At a meeting of this society on Feb. 17th a paper on Observations of the Upper Atmosphere at Aberdeen by means of Pilot Balloons was submitted by Mr. A. E. M. Geddes. A paper from Mr. V. G. Anderson, of Melbourne University, was also read on the Influence of Weather Conditions upon the Amounts of Nitric Acid and of Nitrous Acid in the Rainfall at Melbourne, Australia. The author described the methods adopted and stated that the results of the daily determinations from Nov. 1st, 1912, to Feb. 28th, 1914, when correlated with the meteorological data for Melbourne and the isobaric charts for Australia, reveal the existence of a relation between weather conditions and the amounts of the nitrogen acids in the rainfall. The concentration of nitric acid reached a maximum in summer, a minimum in winter, and an intermediate position in autumn and spring. The concentration of nitrous acid reached a maximum in winter and a minimum in summer. Nine well-defined recurring types of rainstorms have been investigated, the amounts (pounds per 1000 acres) of oxidised nitrogen per day varying from 1.5 in the case of certain antarctic storms to 35.0 in the case of intense tropical storms.

DELAY IN NOTIFYING TUBERCULOSIS.—At Houghton-le-Spring (county Durham) police court recently Mr. W. H. Condell was summoned under the Public Health (Tuberculosis) Regulations, 1912, for failing to notify a case of tuberculosis within 48 hours. Mr. Condell had attended the case on Dec. 14th, 1914, but notification of it had not been received by the district medical officer of health, Mr. D. S. Park, until Jan. 4th. Upon this Mr. Park had written to the defendant asking for an explanation but had received no reply, nor had the clerk to the district council who wrote subsequently. The defendant, who acted as assistant to two medical practitioners practising in partnership, stated as an explanation of the delay that he had made out the notification and addressed it, but that it had been mislaid and not found and posted until the beginning of January. In this he was corroborated by a dispenser. The defendant also stated that he had been unable to read the letter of the medical officer of health, and that he did not see why the clerk to the council should have written to him as he believed that the notification had been duly sent. The magistrates had been informed by Mr. Park that due consideration would have been given by the council to any explanation before taking proceedings, and no doubt had this omission to reply in their minds in imposing a fine of £3 and costs, including £2 2s. for the fee of the prosecuting solicitor, with the alternative of a month's imprisonment in default of distress.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 27, 1915.

Radium Therapeutics.

THE annual report of the Radium Institute dealing with the work done during the year 1914 is before us, having been issued with commendable promptness. It differs from that of the previous year in being more comprehensive, and details of technique and of actual cases are given to an extent not attempted before. From the abstract which we publish in this issue it will be seen that the report does not vary much from the reports issued in former years in its main features, but we have now the records of many cases in which radium emanation has been largely employed, and also records of a few instances of rare conditions which have proved amenable to radium therapy. The total number of cases is somewhat smaller—841 as against 972 in 1913. Ninety-five were examined but not treated, and of the remaining 746 cases 429 were malignant, including 73 of rodent ulcer. As in the previous report none are stated to be cured, but we have the same number as in the last report, viz. 50, given among apparent cures. Owing to the smaller total number in the present report we obtain a slightly better percentage among the apparently cured. On the other hand, in the percentage of those described as "improved" there is a decline to a corresponding degree. From this we may say that as regards this treatment of malignant disease we are broadly in the same position as we were a year ago. While it would have been more satisfactory to be recording some definite advancement, there is no reason for disappointment. Real advancement in radium therapeutics must be slow; it is quite conceivable that taken in bulk the cases in 1914 were slightly less favourable than in 1913, though in both years the patients were as a whole in an advanced state of disease. And speaking generally, it must be remembered that in radium therapeutics we are concerned with some of the most difficult pathological problems that have ever confronted the medical profession. The work of the Radium Institute has proved valuable as well as suggestive, and its utility will surely develop with time and experience.

Carcinomata affecting moist mucous membranes still continue to be very refractory in their response to radium, but we note that a new method of attack is being tried which promises well. It consists in burying within the nodule a very small but intensely powerful emanation tube. The reaction is severe, and in some of the cases the nodule ceases to grow and becomes replaced by fibrous tissue. Unfortunately, neither here nor in other situations does the application have any

influence on metastasis, and it is this unfortunate property of malignant growths that marks the most serious limitation to radium therapy, since a large proportion of these inoperable cases must be near to the stage of dissemination—some indeed have actually entered upon it. Excellent results continue to attend the radium treatment of carcinoma of the uterus, much more so than when the rectum is attacked; and especially is this the case when the site of the growth approaches the sphincters. In a few instances carcinoma of the prostate has been treated with results that are very hopeful. With regard to the sarcomata, it is pleasing to note that the outlook is distinctly more encouraging; as a rule, if they are submitted to early treatment these growths do very well under radium treatment. Those situated in the tonsil and post-nasal space seem to be particularly benefited, but in all cases the treatment must be vigorous. Non-malignant growths react so favourably that an almost unbroken series of successes is presented in the report, and the same may be said of many skin diseases which resist most ordinary methods of treatment; this is particularly noticeable where much itching is present, such as in lichenification of the skin and in pruritus. It is of interest to record that considerable success has attended the treatment of angio-neurotic oedema—a comparatively rare disease that has resisted other methods of therapy. A striking feature of the work of the past year has been a large increase in the number of cases of arthritis deformans treated by the daily administration of a definite quantity of radium emanation solution, with results that are quite remarkable. Early cases in subjects under 40 years of age respond most favourably, especially where the changes are peri-articular. Increased mobility, diminished pain and grating, restored muscular tone, and improved general health have been noted in a large proportion of cases. Considering what an obstinate, painful, and crippling disease this is, these results constitute no mean achievement; they may bring relief to thousands of sufferers. It will give some idea of the extent of the work at the Radium Institute when it is stated that the number of treatments given last year was no less than 6453, and it is gratifying to record that more than half (3972) were given free of charge to necessitous patients.

The report of the work done in the radium department of the Edinburgh Royal Infirmary during the same period has also just been issued, and we publish a summary of it this week. While naturally the total number of cases treated is very much smaller, the results, generally speaking, are the same as in the case of the Radium Institute, at least so far as treatment by means of tubes and plates containing radium is concerned. The use of emanation tubes and solution apparently has not yet been attempted in Edinburgh, if we may so judge from the absence of any reference to this in the report. Altogether we are of the opinion that the result of the year's work in radium therapy discharged by these two institutions is very satisfactory, and that great credit

is due to Mr. HAYWARD PINCH and Dr. DAWSON TURNER for the sound and scientific manner in which this important work has been carried out in their respective jurisdictions. From time to time the scarcity and price of radium have given rise to considerable comment, and probably these factors are responsible for many individual sufferers being denied the benefits they might have secured. We are not sure that this is altogether to be regretted in the case of a powerful agent such as radium. The requisite quantities for serious work and investigation could be obtained only by means of co-ordinated wealth, and this has ensured the work being entrusted to experts possessing the necessary qualifications, whose co-ordinated efforts are likely to advance our knowledge far more rapidly than would the unregulated efforts of the profession at large; also the possibility of harmful effects arising from its use in unsuitable cases is reduced to the minimum. Should the time come when a plentiful and cheap supply of radium is available we shall have every reason to be thankful for the admirable investigations made under present conditions.

In conclusion, while we are glad to pay tribute to the excellent work and progress made in radium therapy, we should not forget that in the X rays we have an agent that has done us good service in the past but whose possibilities are by no means exhausted. The exhibition of cases of uterine cancer, treated by radium, which took place at the Royal Academy of Medicine in Ireland at the last meeting of the Section of Medicine, led to a debate of some significance in this direction. The question of immunity to malignant disease following upon the use of radium emanation, here touched upon, is one that fully deserves further attention. Again, some remarkable results have been obtained through the use of massive doses, heavily screened, and applied to deeply seated malignant growths. It is not unlikely that the therapeutic applications of the X rays and radium will each become relegated to certain classes of work and much of the present overlapping avoided. Individual idiosyncrasies will have to be met, but in the main the two agencies should be considered as complementary rather than antagonistic. From all of which it will be seen that much earnest work remains to be done.

The War and Industrial Pharmacology.

IN more directions than one the war is opening up joints in the harness of the nations. One of the difficulties that has made itself felt in nearly all countries except Germany is a shortage in the increasingly important class of synthetic products used in medicine. This is one of the directions in which it has been urged that we should endeavour to capture the enemy's trade, for we have unwisely allowed Germany to establish a practical monopoly of these drugs. This matter is also forcing itself

upon the attention of our French colleagues, as is evidenced by an extremely interesting address by Dr. EDOUARD BARDET, of Paris, the new President of the Société de Thérapeutique,¹ on Jan. 13th.

Dr. BARDET suggests that the reason why this industry has been captured by Germany is that favourable legislation has been enacted and invaluable assistance rendered by the universities in the solution of industrial problems. With this backing German capitalists have not hesitated to embark the all-essential capital in the development of this industry. Dr. BARDET goes on to point out that in Germany men of science of the highest calibre have not considered it beneath their dignity to devote their energies to the work. In France, on the other hand, the opposite has been the case, and French men of science have shown a systematic indifference to industrial pursuits. Dr. BARDET also insists that the French pharmacy law, which was framed practically before any chemical industry existed, and forbids the manufacture of pharmaceutical products except by pharmacists or under their control, has been a powerfully deterrent factor. In the circumstances, he says, capitalists not unnaturally decline to sink large sums in an industry in which they are personally debarred from controlling the expenditure of their money. In his opinion it is largely due to these causes that the manufacturing side of synthetic chemistry has been neglected in France, and he gives one instance which serves to show that while industrial enterprise has been kept in check initiative has not been wanting. The case he cites is that of the drug which is so well known under the German trade name of urotropin. In 1894 Dr. BARDET, in conjunction with TRILLAT, first called the attention of the profession to its therapeutic uses and suggested for it the trade name of formine. This name was public property, and any chemist or pharmacist was free to manufacture the drug and put it on the market in that name. It was not, however, until the German house of Schering, as a result of Dr. BARDET'S labours, produced and popularised the drug under the name of urotropine that the French medical profession paid attention to it, with the result that France for 20 years has paid to Germany an annual tribute of hundreds of thousands of francs for an ordinary drug of French origin which could have been sold at much lower prices when freely manufactured under its chemical name or that of formine.

That someone or something is to blame for this state of affairs is obvious, but whether Dr. BARDET places the blame in the right quarters is at least open to question. In England a good many people have selected the cost of alcohol as the scapegoat, but Dr. BARDET'S scapegoat is apparently the archaic pharmacy laws. Again and again he points to the restrictions imposed by the pharmacy laws as being responsible for the neglect of the manufacture of

¹ Bulletins et Mémoires de la Société de Thérapeutique.

synthetic drugs. But is he right? It is true that the French law which regulates the practice of pharmacy is in urgent need of amendment, but as no doubt Dr. BARDET knows, the administration of the law in France is tempered with a good deal of common sense, and a good many things are done openly, and apparently with the full sanction of the Government, which if tested would be found to be technically illegal; in fact, he instances one such case himself—namely, the manufacture of bromides, which is carried on in France by makers who are not pharmacists, because bromides are used in photographic processes. Those who have had personal experience of the working of the French pharmacy law, and of the indulgent attitude of those who administer it, can hardly have failed to form the opinion that if any of its provisions really stood in the way of real progress their application would be rendered obsolete. What seems to have been overlooked is that the manufacture of coal tar colours, of which industry the manufacture of synthetic drugs is merely an offshoot, has been neglected in France almost as much as in Great Britain. Yet there is nothing in the French pharmacy law to prevent people who are not pharmacists from manufacturing dyestuffs. While one cannot but think that Dr. BARDET has found the wrong scapegoat, it can readily be acknowledged that he has done a useful service in drawing attention to the defects of the pharmacy law, for it would be a very serious matter if the progress of this industry should be impeded even slightly by restrictive legislation of an unnecessary kind. Dr. BARDET also blames the comparative indifference on the part of the medical profession in France as being partly responsible for the neglect of the synthetic drug industry; but here, again, it is doubtful whether his view is altogether a just one. It must be remembered that synthetic drugs were not made to supply a demand, but that the demand was created to meet the supply. The real causes of the neglect of the fine chemical industry in France have been much the same as in this country—namely, the failure of our manufacturers to make use of the services of technical chemists and the failure of the Government to subsidise chemical research, and to encourage manufacturers to apply the discoveries of the laboratory to industrial problems. Happily there are distinct signs that in this country at any rate our manufacturers now recognise their mistakes, and what is equally important, we have the assurance that the Government is willing to grant a very substantial sum for the purpose of experimental work in connexion with the production of coal-tar colours. And as the chemistry of these colours is so intimately related to that of synthetic drugs it seems clear that the production of these drugs will progress with the progress of the dyestuffs industry. No doubt the French Government is equally well aware of the needs of the industry and will take the steps which seem to be indicated.

Annotations.

"Ne quid nimis."

REGULATIONS PROHIBITING THE SALE OF DANGEROUS SHELL-FISH.

THE Local Government Board has just issued an Order, under the Public Health (Regulations as to Food) Act, 1907, to take effect on March 1st, to enable the local authority of any port or sanitary district which comprises tidal waters to prohibit the sale of shell-fish taken from any public or private laying, when evidence is forthcoming that the consumption of the shell-fish is likely to cause danger to public health. The prohibition is to be made on the advice of the local medical officer of health, and in all cases the owner or fishmonger is to be given the opportunity of relaying the shell-fish, for purposes of purification, for such periods as the medical officer of health advises to be necessary. This period, in the case of contamination with sewage organisms, will usually be at least a fortnight. The action may be taken on local evidence alone or as the result of representations to the local authority by some other authority in whose district shell-fish from the suspected laying are sold. Medical officers of health may in some cases find it difficult to determine what degree of risk of possible sewage contamination will justify their application of the new powers, but fortunately the main facts are well known and the principles of action are now generally agreed upon. The opportunities of pollution of oyster layings and of beds of cockles, mussels, and other shell-fish all round the English coast were very fully described in the late Dr. H. T. Bulstrode's well-known reports of 1894 and 1911 to the Local Government Board, while the whole question of polluted shell-fish was thoroughly investigated by the Royal Commission on Sewage Disposal, and discussed in its fourth report. In the great majority of cases in which outbreaks of disease have been attributed to shell-fish, the foreshores, layings, or ponds have been so situated that opportunities of pollution by sewage have been obvious and indisputable on physical examination alone, bacteriological tests of the water or the shell-fish being almost unnecessary for proof of the occurrence of such opportunities. The efforts which have been made by oyster merchants, with the powerful aid of the Fishmongers' Company, to secure the general wholesomeness of oysters in this country have largely depended for their success on the elimination of oysters from all layings where such obvious pollution has been liable to arise, and it may be hoped that the new regulations will cause a corresponding degree of precaution to be taken in respect of sewage-polluted cockles and mussels, which in recent years have been much more frequently accused of producing enteric fever than have oysters. In a circular to the local authorities concerned the Local Government Board indicates that it has not yet been possible to alter the law in regard to the supervision of the purity of rivers and estuaries in the way recommended by the Royal Commission, and that the new regulations, which have to be enforced by existing local authorities, are to be considered as an alternative adopted to meet present needs as far as possible under existing powers. At a time when every precaution should be taken to minimise all sources of enteric

fever infection this action of the department will be welcomed. The regulations provide for appeal to the Local Government Board, and thus should secure that in any case of difficulty the question of prohibiting the sale of shell-fish from suspected layings will receive careful expert examination.

WAR AND EUGENICS.

THE relation of war to eugenics is quite naturally forcing itself at present very strongly upon the attention of the eugenicists. In the United States thoughts were turned in that direction the moment the magnitude of the struggle was envisaged. Professor Starr Jordan, of Stanford University, California, has delivered a notable address upon Eugenics and War, and the same subject occupied the attention of Mr. Theodore Chambers in a lecture delivered last October before the Eugenics Education Society.¹ Now the second Galton lecture, delivered before the same society in memory of the late Sir Francis Galton on his birthday, Feb. 16th, by Mr. J. Arthur Thomson, Regius professor of natural history in the University of Aberdeen, has taken up the same subject, and almost necessarily follows much the same lines as those of Mr. Chambers. Professor Thomson emphasised the fact that those who see in warfare a eugenic influence along the line of the struggle for existence lose sight of the difference between the effect of tribal warfare and modern wars, in that while the former eliminated the weak and cowardly the latter takes special toll of the virile and courageous. The struggle for existence is often misunderstood, moreover, through its limitation to the one aspect of sharpening tooth and claw, whereas other modes of response to the limitations and difficulties opposed by environment, such as the fostering of parental care, the subordination of self-preservation to the interests of the race, and (especially among the finer forms of life) a movement towards coördination rather than competition as favouring survival and success, are overlooked. In this respect war appears biologically rather as a reversion to the most primitive and crude form of the struggle, and involves a serious danger of descent in the scale of evolution. Professor Thomson, with a view to counteracting this, suggests that the tendency to economise in the "nobler luxuries" should be resisted, as crippling the least readily replaceable members of the community. It is interesting to recall here that the distress among professional classes caused by the war, which will inevitably be heavier and will endure longer after peace is declared than with most other sections of the community, has led to the formation of a Professional Classes War Relief Council (13 and 14, Prince's-gate, S.W.), which aims to organise assistance by the coöperation of professional institutions and societies organising relief, not in the way of charity but by giving centralised forms of aid in such matters as education, training, emigration, maternity, and temporary employment, and generally by rendering assistance to the dependents of professional men who have enlisted or have been called on to serve in their Territorial units. In the matter of education especially, measures will be taken to enable such dependent children to go to or continue at school when their education

would otherwise be interrupted. A great point in favour of this scheme is the fact that its organisation need not be transitory and limited to the duration of the war, for many of the methods indicated in the council's programme will possess permanent utility. The personnel of the council will command general confidence, which will be heightened for the medical profession by the presence thereon of well-known medical men. Professor Thomson in his address further recommends the encouragement of marriage among soldiers, where adequate provision for widows and dependents is forthcoming, and urges a jealous scrutiny of the various well-meant but hasty proposals for relieving war strain, such, for instance, as the suggested employment of children in agricultural labour. It must be remembered, however, that all available men may be needed for service, while the stoppage of agricultural pursuits would be as disastrous as a defeat. The outdoor healthy life of agricultural work for children can scarcely be condemned as that in shops and factories might justly be. Compulsory military training Professor Thomson regards as a lesser evil than a large standing army, but fears its possible effect in Prussianising the people. Above all he urges strenuous resistance against any lessening of eugenic endeavour in consequence of the war.

MEDICAL PRETENSIONS IN AMATEURS.

WE have before us two curious leaflets. One is headed "The Eustace Miles System, Revised List of Fees (payable in advance or at the time of interview), for the Various Health, Diet, Exercise, and Mind-training Courses, Threefold, Twofold, and Blood Examinations, Interviews, &c., &c."; the other is entitled "In Time of War," and in it "The Health and Medical Reform League" advertises an At Home to be held at the Eustace Miles Restaurant, when short addresses, music, and tea are promised to the company. Both of these documents appear to us to have the same objectionable feature in that they endeavour to attract by the pretension of qualification to advise upon matters which in general experience are best treated by those having medical knowledge. We have no criticism to offer of the fitness of Mr. Eustace Miles to deal with all things strictly relating to the ball games of which he is a proficient and well-known exponent, and his personal knowledge of how to train for these games has its value; but we very strongly deprecate the introduction of a marked medical flavour into a commercial advertisement issued by any person not having professional training. Of course, if Mr. Miles did possess medical qualifications he would be debarred from issuing any advertisement at all, whether in the form of a list of fees or otherwise. We quote from Mr. Miles's tariff sufficient to indicate the kind of matter which we consider objectionable, not only as a subject of advertisement, but as an invitation to persons who may be in need of medical treatment, or who fancy themselves so, to seek the advice of the unqualified. There are more than 20 items in the menu which he offers, and if many are harmless the following cannot be without risk.

A. For the First Threefold Examination and Report, with full Health Course (Diet, Exercises, Mental Helps, Water-treatments, &c.), and a Personal Interview with Mr. Eustace Miles lasting for about 30 minutes: Five Guineas.

C2. For each Blood Examination and Report, with General Advice (see G.) and a Personal Interview lasting for about 30 minutes: Three Guineas.

¹ Eugenics and War, by Theodore Chambers, *Eugenics Review*, January, 1915.

D. For each examination of only the Urine and Excreta (for which Mr. Collings sends special postal tins, &c., with full instructions) and report and general advice (see G). Two guineas.

We gather under "G" that general advice is given by correspondence, and includes considerable but not full advice, and under "H" that for a guinea there can be had a personal interview lasting 30 minutes, to include "as much practical advice as can be given in the time." At a special fee blood examinations may be made at "patients' own houses." Under the head of cookery there are offered lessons and "remedial recipes," presumably not administered personally by Mr. Miles, for "the cure of gouty and rheumatic disorders, liver and kidney troubles, anaemia, &c." "Single lesson (4 or 5 recipes for one complaint) 5s." The food provided by Mr. Miles at his restaurant may be wholesome, and some palates may find it agreeable, but such catering does not constitute a scientific training. Many people eat more than is good for them and consume food which they had much better avoid, but we must express without qualification the opinion that anyone whose state of health renders examination of his blood, urine, or faeces desirable had better place himself in the hands of a medical practitioner, and receive such advice as to diet as his case demands. If any of the articles of food thus recommended are to be obtained from the establishment which bears Mr. Miles's name, then, no doubt, it will be found an excellent place at which to purchase them. The second document does not in any way mention Mr. Miles, but is the advertisement of a meeting for the delivery of "Short Addresses on 'International Importance for Helping Soldiers and Others under Nerve Strain, by Modern Methods of Nursing and Diet.'" The speakers named are a Mr. Maitra, a Miss Beadon, and a Mr. T. Butt. The qualification of the last named alone is given. He is described as "late Private, Grenadier Guards," and may have had personal opportunities for the observation of nerve strain in soldiers. But the point is that no one without real knowledge of physiology and psychology can have anything to say upon the subject that is worth hearing, and this is not the right time to invite general audiences to listen to any teaching upon so critical a subject as nerve strain in soldiers, save from men and women of the highest equipment. Mr. Eustace Miles could, we think, put his restaurant to better uses.

ANTHROPOLOGY OF THE AFRICAN BANTUS.

Mr. G. D. Maynard and Dr. G. A. Turner¹ have utilised the opportunities afforded them by their connexion with the Witwatersrand Native Labour Association to collate a comparatively large number of anthropological records on Portuguese East African natives recruited for work on the gold, diamond, and coal mines of the Transvaal. The authors give a historical sketch of the various native races, divided into two main classes: (1) the subtropical or East Coast natives, from between the Zulu border and latitude 22° S., and (2) tropical natives, from between the Zambesi river and German East Africa. The first group contains the Shangaans, Mytopis, Inhambaans, and Maputos or Tongas; the second, the Agoni and

Agawa from the Pete district, the Quilimanes, Mozambiques, and Portuguese Nyassas. Accuracy of detail being out of the question, the authors have attempted merely to give the reader some idea of the nature of the material, and to demonstrate the futility of attempting to regard any tribe as a pure strain, even if only for a few generations; for tribal wars are frequent and the predominant tribe leaves its mark on the inferior race, since all marriageable females become the property of the dominant race. Other influencing factors in intermingling are the exchange of women among chiefs, the slave trade, and the Portuguese policy of bringing black soldiers from one colony to another and of deporting chiefs and their followers from one part to another. Examinations of the actual data obtained from post-mortem examinations of natives show very marked differences between the natives from tropical districts and those coming from south of lat. 22° S., and even on subdividing these groups differences are still discernible, though to a less extent. Descriptions and tables of the data obtained follow under the heads of stature, brain weight, skull thickness (in which connexion it is noticeable that no evidence is forthcoming to lend weight to the contention that the native skull is thicker than that of the European), cephalic and cranial indices, scalp measurements, heart, spleen, liver, and kidney weights, and intestinal measurements. Some excellent drawings by Miss O. M. Vieick depict the faces of various natives typical of their races, and illustrate the facial markings that form a noticeable feature among many Bantu tribes. Outside scientific work of this character by medical men is worthy of all commendation.

THE MEDICAL EDUCATION OF WOMEN.

ON Thursday in last week a meeting was held in Sunderland House, Curzon-street, London, the hostess, the Duchess of Marlborough, presiding, when the object was to promote the extension of the London (Royal Free Hospital) School of Medicine for Women. The Duchess of Marlborough in opening the proceedings dwelt upon the shortage of medical practitioners already felt in this country, a shortage which must inevitably increase as military exigencies make even greater demands upon a limited supply, and pointed out that the laments of medical women to a wider and more energetic public support were accentuated by the emergency. The view is one that we all support. Sir Donald MacAlister made a statement recently at a meeting of the Executive Committee of the General Medical Council to the effect that for the next few years from 200 to 300 fewer medical men will qualify as medical practitioners, and his statement was communicated to the War Office in order that senior medical students serving in the Army in different capacities might be released and enabled to continue their studies. In this way the more immediate shortage may be alleviated, but the position in the years to follow must remain unaltered. The medical curriculum occupies the student on an average at least six years, so that no reinforcement in our medical schools will be reflected upon the Medical Register until 1920 or so. The shortage would have been inevitable in any case, and in face of contradiction we have frequently said so; the war bids fair to make it acute by increasing the demand and diminishing the supply. This affords a great opportunity to medical women, and there is no

¹ Anthropological Notes on Bantu Natives from Portuguese East Africa. By G. D. Maynard, F.R.C.S. Edin., and G. A. Turner, M.B., B.Ch. Aberd., D.P.H. Johannesburg: The South African Institute for Medical Research. 1914. Pp. 36 + 14 plates. Price 2s. 6d.

doubt of their intention and ability to use it. For with them the numbers of recruits are increasing instead of decreasing, while the openings for practice have been vastly enlarged, every bit as much in acknowledgment of the sterling services rendered by medical women as because the exigencies of the times have made new avenues free to them. Medical women are now serving the public in hospitals, in private practice, in pathological laboratories, as medical missionaries, in Government departments, and in municipal bureaux, and in all their various capacities are justifying their positions. And in the war they have made their mark. The Director-General of the Army Medical Service at the Sunderland House meeting said that his opinion of the work done by the medical women on the staffs of their hospitals at Paris and Boulogne had been so favourable that he had specially given certain of them larger responsibilities; the impressions of Sir Alfred Keogh have received confirmation on all hands, and his expressed intention of making greater use of medical women in connexion with the war has been generally approved. In asking the public, therefore, to support the extension of the London School of Medicine for Women the promoters of the movement are on the surest of ground—the services of the medical women are required, and they have proved that these services are of great value to the community. The medical education of women largely centres round the London School of Medicine for Women, where more than half the women practitioners on the Register received their education, and no more worthy object of public support, both on general and scientific grounds, has ever been brought forward than this school. £25,000 is asked for, but much more might well be given.

THE Friday evening discourse on March 11th at the Royal Institution will be given by Sir Rickman J. Godlee on "Back to Lister."

Sir Richard Douglas Powell, Bart., will deliver an emeritus lecture, entitled "A Case of Congenital Heart Disease," on Friday, March 5th, at 3 P.M., in the new theatre of the Middlesex Hospital Medical School.

WE regret to announce the death of Dr. Edward Cox Seaton, which occurred on Saturday, Feb. 20th. Dr. Seaton, who was consulting medical officer of health to the Surrey county council, had been throughout a long professional life a prominent and active sanitarian.

A CLEARING HOSPITAL FOR WAR REFUGEES.—At the request of the Local Government Board a dispensary and small hospital for war refugees has been opened in Sheffield-street, Kingsway, W.C., under the control of the Metropolitan Asylums Board. A large building, admirably suited for the purpose, has been fitted up with all the necessary requirements for a dispensary, and hospital accommodation has been provided for 21 beds, with possibilities of extension to 24, while in addition six cubicles can be used as observation or isolation wards. On the ground floor are a large waiting-room, a dressing-room and dispensary, and offices for the medical and nursing staff. Should occasion arise the accommodation can be considerably extended. The institution is intended to act as a clearing house, where cases may be kept under observation and treated prior to being drafted to other institutions. The medical officer who has charge of the hospital and dispensary, Dr. D. F. Riddell, is being assisted by Dr. G. DeLaey, a Belgian medical man. Special cases receive the attention of the specialists attached to the Metropolitan Asylums Board.

CEREBRO-SPINAL FEVER: A MEMORANDUM FROM THE LOCAL GOVERNMENT BOARD.

OCCURRENCE OF THE DISEASE.

A MEMORANDUM of the first importance upon the incidence of cerebro-spinal fever, its clinical features, and the administrative action that should be taken against its spread, was issued on Wednesday morning by the Local Government Board to the medical officers of health and sanitary officers of this country. The Memorandum has been prepared by Dr. Arthur Newsholme, medical officer of the Board, in view of the recent occurrence of the disease in various districts, and is a revision of the Memorandum first issued by the Board in 1905 and reissued in 1910. After a brief résumé of the outbreaks of the disease at earlier dates, the Memorandum continues:—

Incidence of the disease.—In this country seasonal incidence of the disease has not been marked, but there has been some increased prevalence of the disease in winter and still more in the spring. This has been much more marked in Continental and American experience. Amongst the civil population in this country and in such epidemics in other countries the majority of the cases have occurred in children. During 1912 there were notified in England and Wales 272 cases,¹ during 1913, 304 cases, and during 1914, 310 cases of this disease. It is possible that some of these cases were meningitis due to other micro-organisms than the meningococcus, and that some cases regarded as cerebro-spinal fever were poliomyelitis. On the other hand, it is not unlikely, in view of the difficulty of diagnosing sporadic cases, that unrecognised cases of cerebro-spinal fever may have occurred.

Clinical features of the disease.—The late Mr. Netten Radcliffe described cerebro-spinal fever as "an acute, epidemic disease, characterised by profound disturbance of the central nervous system, indicated at the onset chiefly by shivering, intense headache or vertigo, or both, and persistent vomiting; subsequently by delirium, often violent, alternating with somnolence or a state of apathy or stupor, an acutely painful condition with spasm—sometimes tetanoid—of certain groups of muscles, especially the posterior muscles of the neck, occasioning retraction of the head and an increased sensitiveness of the surface of the body. Throughout the disease there is marked depression of the vital powers, not unfrequently collapse, and in its course an eruption of vesicles, petechial or purpuric spots, or mottling of the skin is apt to occur."² If the disease tend to recovery, the symptoms gradually subside without any critical phenomena, and convalescence is protracted; if to a fatal termination, death is almost invariably preceded by coma. After death the enveloping membranes of the brain and spinal cord are found in a morbid state, of which the most notable signs are engorgement of the blood-vessels, usually excessive, and an effusion of sero-purulent matter into the meshes of the pia mater and beneath the arachnoid."³ Local prevalence of illness distinguished by the foregoing features would, no doubt, attract attention and would, it may be presumed, lead to early recognition of its true nature. But while these features are characteristic of typically severe cerebro-spinal fever, experience shows us that it may and does appear in milder or in anomalous forms which render identification difficult, and which lead to its being mistaken for other ailments of more common occurrence in this country. Illustration of this is afforded by certain localised outbreaks of cerebro-spinal fever in the eastern counties in 1890, where this disease was generally mistaken for sunstroke or for enteric fever, or was looked

¹ The disease was made notifiable for the entire country from Sept. 1st 1912. Prior to this it had been notified in a number of sanitary areas.

² In a very considerable number of instances, however, no eruption of any kind is present.

³ To the clinical manifestations of the disease indicated in the above description may be added the presence of Kernig's sign and of tache cérébrale.

upon as a new form of illness; by the prevalence of what would seem to have been cerebro-spinal fever in Northamptonshire in 1890-91, where the malady was for the most part diagnosed as pneumonia or as sore throat; and by the occurrence of cerebro-spinal fever in Irthlingborough in 1905, where many of the persons attacked were regarded as suffering from influenza. In these anomalous forms of cerebro-spinal fever, many or even most of the symptoms associated with the recognised type of the disease may be absent, while in mild cases they may be so slight or of such brief duration as to escape notice. It is necessary to be on the outlook for such cases when cerebro-spinal fever occurs in a locality or when illness not clearly referable to definable cause prevails in a particular neighbourhood. Cerebro-spinal fever is apt also to escape recognition when it is of the "fulminant" variety, in which death ensues rapidly. In these instances the disease has been mistaken for typhus fever, idiopathic tetanus, malignant measles, or other diseases.

Mode of spread of the disease.—Cerebro-spinal fever has a much more restricted direct infectivity than characterises a disease like small-pox, which attacks the majority of persons exposed to infection who are unprotected by vaccination or previous small-pox. In most outbreaks of cerebro-spinal fever only one member of the invaded family develops definite symptoms of meningeal disease, though exceptions to this statement are not uncommon. The meningococcus is found in the mucous secretion of the nasopharynx in a considerable proportion of those suffering from the disease, especially in its earlier stages, and also in some apparently healthy persons who have been in contact with cases of the disease.

The Memorandum continues by pointing to the probability of carriers of infection existing who are themselves unaffected, and while admitting that modes of infection as yet unrecognised possibly exist, concludes that cerebro-spinal fever generally spreads in association with overcrowding, lack of cleanliness and ventilation, inclement weather, and perhaps excessive fatigue.

ADMINISTRATIVE ACTION.

The second part of the Memorandum deals with administrative action, and commences by pointing to the necessity of careful diagnosis between cerebro-spinal fever and poliomyelitis, both of which diseases are compulsorily notifiable. The advisability also is mentioned of making inquiry into the circumstances of deaths recorded as tuberculous meningitis, meningitis, or convulsions (with no further definition) when these deaths occur in districts where cerebro-spinal fever is known to be present, while medical officers of health are recommended also to invite from practitioners details as to anomalous cases of sickness which might be cerebro-spinal fever.

The Memorandum then points out the necessity of employing bacteriological aids to diagnosis.

In view of the difficulty of diagnosis of early cases of the disease the Board are prepared to undertake the examination in their pathological laboratory of cerebro-spinal fluid sent to them packed in accordance with the regulations of the Post Office. The parcel should be addressed to the Medical Officer, Local Government Board, Whitehall, and should be accompanied by a short statement of the circumstances of the case. The hour at which the specimen was collected should be stated, and delay in transmitting the material should be avoided. The patient is also to be strictly isolated, carefully nursed, and all precautions are to be observed as to disinfection, both during the patient's illness, and later when the sick-room is vacated.

The Memorandum continues:—

Investigation of sources of infection.—The possible occurrence of anomalous cases should be investigated. Special

attention should be directed to cases of sore-throat, headaches, pains in back and limbs, &c., suggesting "influenza." The important share borne by healthy "carriers" as agents of infection should be borne in mind. The bacteriological examination of swabs from persons likely from their history to have acted as "carriers" should be undertaken. The method of procedure is set out in the next paragraph.

Investigation of possibilities of continued infection.—The infectivity or otherwise of contacts can be determined by taking swabs from the upper part of the nasopharynx. Swabs from the fauces are of small value. It is important to avoid contamination of the swab by the bacteria of the mouth and fauces. This has been effected by using a swab mounted on a long rod, curved at its distal end, and protected by a metal cannula. The swab should not be extruded until the end of the cannula has passed behind the uvula, and should be withdrawn into the cannula immediately after careful contact has been made with the mucous membrane of the nasopharynx. As the meningococcus does not live long in the swab it is desirable that Petri dishes containing suitable media should be obtained direct from a laboratory and inoculated directly the swab has been taken. The first Petri dish may become overgrown with extraneous organisms, and it is therefore desirable to use two dishes, the second being inoculated from the first by means of a sterile glass rod or other sterile implement. The Petri dishes should be forwarded to the laboratory without delay. Whenever practicable swabbing should be done by or under the superintendence of the bacteriologist. Inability to secure a positive result from swabbing may be caused by unskilled swabbing or by failure in the subsequent procedure of inoculation of the medium in the Petri dish or by failure to incubate promptly at the appropriate temperature. Negative results obtained with swabs sent by post for transfer to culture media at a laboratory may be due to the death during transit of any meningococci present.

Precautionary measures as to contacts.—All persons who have been in attendance on, or otherwise in close personal association with, the patient should be regarded as possible carriers of infection. The duration of the infectivity of contacts is doubtful. It will be a useful rule to regard them as possibly infective for three weeks from the date of last association with a patient, but the partial restrictions to their intercourse, otherwise desirable, may be relaxed if swabs from the nasopharynx examined under the conditions set out in the foregoing paragraph fail, preferably on two occasions, to show the presence of the meningococcus. Contacts should be instructed and warned that they may be a source of danger, although remaining quite well themselves, and that for this reason they must abstain from intimate personal association with others. This rule should be especially followed by contacts who have catarrh. Contacts should also be advised that an open-air life diminishes the risk of infection both of themselves and of others. Isolation of such contacts in a hospital should not be attempted. Detection of the meningococcus in the nasopharynx of a contact is valuable evidence of his potential infectivity to others, while failure to find the micro-organism does not possess an equal negative value. Nasal sprays have been recommended for contacts, a disinfecting solution such as potassium permanganate, 1 in 1000, being used. If spraying is employed it should be carried out under medical supervision.

General preventive measures.—In the presence of cerebro-spinal fever the nearest approach to open-air life should be aimed at, especially for all contacts. In view of the known association of cerebro-spinal fever with overcrowding, insufficient ventilation, and uncleanness, the avoidance of these conditions becomes a matter of prime importance. This is especially true where large numbers of persons are aggregated under one roof.

A covering letter to Dr. Newsholme's Memorandum, signed by the Assistant Secretary of the Local Government Board, requests that medical officers of health will forward to the Board, addressed to the medical officer, a report on each case of cerebro-spinal fever notified in their districts, and a schedule is appended to the Memorandum indicating the form which the information should take.

REPORT OF THE RADIUM INSTITUTE FOR 1914.

Mr. Hayward Pinch's report for 1914¹ deals with the cases which have presented themselves at the Radium Institute from Jan. 1st to Dec. 31st inclusive, and the cases treated were in no instance selected. The only cases refused have been those in which the patients were practically moribund, or where the disease was of a kind for which radium therapy was manifestly unsuitable. The report is of a very comprehensive character, containing details of technique and actual cases under each heading. As a copy will be sent on application to every practitioner who desires it, we abstract only such portions as will give a general idea of the results attained during the year's work.

Carcinoma (Squamous-celled (Epitheliomata)).

Epitheliomata of the face, trunk, or extremities, if flat and superficial and accompanied by little or no ulceration, give satisfactory results when treated with quarter or half strength apparatus, screened with 0.1 mm. of lead, the exposures varying from six to twelve hours' duration, spread over a period of three or four days. The retrogression of the growth is quickly brought about and little or no scarring results.

Ulcerating epitheliomata without much subjacent infiltration require treatment with quarter or half strength apparatus applied unscreened for a total exposure of two to six or eight hours, spread over a period of four or five days, and repeated after an interval of six weeks if necessary. A destructive reaction follows, but the result is usually quite good, and there is but little cicatricial contraction.

Ulcerated epitheliomata with great infiltration require prolonged treatment with heavily screened apparatus emitting only hard β and γ —the so-called "ultra-penetrating"—rays. Exposures of 30 to 60 hours given during one week, and repeated in five or six weeks' time are best; but if the growth shows signs of rapid extension the borders should be given a vigorous treatment with unscreened apparatus.

Epitheliomata of the buccal, lingual, and pharyngeal mucous membranes usually prove both refractory and disappointing in their response to radium, but a new method of treatment has been devised which in instances of cancer of the tongue has given somewhat encouraging results; it consists in the burying within the carcinomatous nodule of a very small but intensely powerful radium emanation tube possessing an initial activity equivalent to that of 80 to 100 mg. of radium bromide, enveloped in a screen of 1 mm. of silver or 0.3 mm. of platinum, and giving an exposure of 24 hours' duration. A fairly severe reaction follows, and in some cases the nodule ceases to grow and becomes replaced by dense fibrous tissue. Unfortunately, however, the treatment appears to have but little effect in arresting the dissemination of the disease, which sooner or later affects the neighbouring lymphatic glands or recurs close to the original lesion. The rate of growth of the infected glands can often be retarded by the prolonged and persistent use of the "ultra-penetrating" rays. If the dose given be a large one, the glands sometimes break down and discharge a milky-white fluid through a small sinus, and it is remarkable that ulceration of glands thus treated rarely occurs. In some of the more favourable cases of stricture of the oesophagus distinct, though temporary, benefit has resulted, and that this effect is not merely mechanical, due to the dilatation of the stricture by the apparatus, is evidenced by the fact that the improvement in the power of swallowing has persisted for six or even nine months after the termination of the treatment.

Detailed notes of four cases are given, the result in each being remarkably successful in view of the gravity of the condition.

¹ A Report of the Work carried out at the Radium Institute from Jan. 1st, 1914, to Dec. 31st, 1914, by A. E. Hayward Pinch, F.R.C.S., Medical Superintendent. (Published with the authority of the Committee.)

Carcinoma of the Uterus.

Uterine cancer continues to yield most gratifying results, and the effects of radium treatment in inoperable cases are far in advance of those obtained by any other known medical or surgical methods. The local manifestations of the disease are benefited in the most striking fashion, and the complete disappearance of fungating growth, arrest of hæmorrhage and discharge, healing of ulceration, and relief from pain are phenomena of frequent occurrence. In favourable cases, moreover, the treatment appears to exert a distinctly retarding influence on the dissemination of deposits, and thus to arrest the progress of the disease. It is not possible, however, to speak of "cure" even in these latter instances.

Carcinoma of the Bladder.

Six cases of this disease have been treated, and in two instances the results have been most gratifying. The hæmaturia, cystitis, and all subjective symptoms have disappeared, and cystoscopic examination has shown that the size of the growth has been greatly lessened, and any ulcerated surface has become covered with healthy epithelium.

Carcinoma of the Breast.

The number of patients with this disease applying for treatment far exceeds that of any other malignant condition. The policy of declining to treat operable cases is still rigidly adhered to, unless the patients have absolutely refused to submit to operation, and radium is used as a last resource. The progress of inoperable, slow-growing cases of the atrophic type is usually much retarded by the use of radium, especially when the metastases are confined to the skin, axillary, and supraclavicular lymphatics, and do not affect the lungs or abdominal viscera. Very small isolated cutaneous nodules on the chest wall, if few in number, may be effectively treated by unscreened exposures of one or one and a half hours' duration with a half-strength radium plate. If very numerous and closely set prolonged exposures of 30 to 40 hours' duration to heavily screened rays are preferable, and this method of treatment should also be resorted to for the primary growth, infected glands, or ulcerated surfaces if such exist. Superficial ulcerations unaccompanied by much subjacent induration are peculiarly susceptible to the action of radium and complete healing of these lesions is frequently observed. Little or no effect appears to be exerted in the prevention of metastatic deposits, though the treatment does not, at any rate, hasten their dissemination. Some cases in which pleurisy or ascites, dependent upon carcinomatous invasion of the pleura or peritoneum, has been present, have shown remarkable improvement, and the application of powerful apparatus screened with 2 mm. of lead over the affected pleura or peritoneum, after a preliminary paracentesis, has effectually prevented the further formation of effusion.

A few patients have been under treatment at intervals of three or four months since the opening of the institute in August, 1911, and it has been observed that a stage in their treatment is reached sooner or later at which the response to radium fails and the benefit derived becomes negligible. In rapidly growing carcinoma of the medullary type radium can do but very little except relieve pain, even though enormous doses be employed.

Carcinoma of the Rectum.

The adoption of radium therapy in inoperable cases of this disease is usually justified by the results obtained, though the amount of benefit is rarely so marked or so great as in carcinoma of the uterus. The disease displays much variation in its response to radium, and numerous factors have to be considered in prognosis. Speaking generally, the soft annular and vascular type of growth is much more favourably affected than the flat, hard, non-annular plaque with much subjacent induration. In the treatment of this latter class of growth the action of the gamma rays (which it is impossible to prevent) on the healthy rectal mucous membrane opposite the plaque produces a proctitis, which though generally transient sometimes proves both persistent and severe, and adds greatly to the patient's discomfort. In the treatment of the former type, if the radium tube be of proper dimensions and introduced accurately within the lumen of the growth, little or no healthy mucous membrane is affected by the gamma rays and no proctitis occurs. Growths situate in the upper half of the rectum appear to

be more amenable to treatment than those in the lower, though this may be due to the fact that tenesmus is always more constant and severe when the growth is near the sphincters.

Carcinoma of the Prostate.

The number of cases of this condition which have been treated up to the present is not very large, but benefit has been noted in all of them. Hæmaturia, when existent, has been either diminished or abolished, pain has been greatly lessened, and the size of the growth decreased.

Rodent Ulcer.

Of all forms of malignant disease this is the one which is most amenable to radium treatment. For the purpose of prognosis it appears justifiable to divide rodent ulcers into two definite clinical types: 1. The hypertrophic nodular type, with slight superficial ulceration of a scaly character. This class responds extremely well to radium and yields most satisfactory results. 2. The excavating type, with undermined and overhanging edges and a gelatinous base. This not infrequently proves very intractable, and repair is most difficult to effect. Increasing experience in the treatment of this condition has strongly confirmed the opinion expressed in a previous report, that the best results were obtained by exposures of one and a half to three hours' duration to full strength applicators unscreened. Although the reaction following upon this procedure is in some cases severe, and accompanied by a transient œdema of the surrounding tissues, the scars are invariably smooth, supple, and inconspicuous, and the tendency to recurrence is exceedingly slight. It is desirable that cases should not have been treated by other methods. Old-standing cases that have been treated by the X rays or CO₂ snow unsuccessfully are always more difficult to treat and the results less perfect.

Sarcomata.

Speaking in general terms, these growths, if taken in their early stages and before dissemination has occurred, do very well under radium treatment. The burying within the growth of tubes of radium salts or radium emanation should be resorted to whenever practicable, and the action of these tubes may be much helped by the external application of radium plates heavily screened. The screening of the tubes should not exceed 1 mm. of silver, as the employment of thick lead or platinum screens is often followed by necrotic changes in the cells in their immediate neighbourhood, and a sinus forms and remains open for a very long time. It is essential to give as vigorous a treatment as possible, as the great vascularity of these growths, and their rapid and wide dissemination by the blood stream, are factors which militate very strongly against the chances of success. The best results are obtained in sarcomata of the tonsil and post-nasal space, and the effect in many such cases is amazing, the growths completely disappearing within six weeks of the treatment. Lymphosarcomata also give excellent results.

Lymphadenoma.

The most striking feature in the treatment of this disease with radium is the extreme rapidity with which the size of the affected glands is diminished, the effect being often clearly perceptible to the patients themselves within a week of the first exposure. To obtain this result, the employment of numerous large and powerful applicators, heavily screened, is necessary, and this heavy dosage is almost always followed by severe systemic disturbance, with high temperature and general malaise. After the reaction has subsided considerable improvement is generally apparent, though in the majority of cases recrudescence occurs. The time at which this takes place, however, varies within very wide limits, and instances have been noted in which the disease has remained quiescent for more than a year. The best results are obtained when the condition is confined to the lymphatic glands—the spleen not being affected.

Splenic Leukæmia.

A case of splenic leukæmia has been under treatment, which began in December, 1913, using flat applicators containing in all 150 mg. of radium, screened with 2 mm. of lead, over the whole splenic area. She was reported quite well in December, 1914.

Adenoma of the Thyroid

A few cases of this condition have been treated during the past 12 months, the patients being unwilling to submit to

operation. In all cases some benefit resulted, and in two the improvement was very marked, the swelling shrinking to less than half size. The treatment has been the same in all instances, powerful flat applicators screened with 2 mm. or 1.5 mm. of lead being applied to the surface of the growth in such a manner as to procure an effective "cross-fire" irradiation. A series of exposures on five successive days, amounting in all to 30 hours, has been given, repeated if necessary at intervals of six weeks or two months.

Fibroid Disease of the Uterus.

Radium exerts a most beneficial action upon the distressing symptoms of menorrhagia and metrorrhagia, which are the almost invariable concomitants of this condition, and occasionally produces considerable diminution in the size of the uterus. As the cervical canal is rarely sufficiently patulous to admit a screened radium tube without previous dilatation, and patients are often averse from this, the treatment may be carried out by the introduction of a tube containing 100 mg. of radium, screened with 2 mm. of lead, into the posterior fornix, and the application of a plate of from 80 to 100 mg. similarly screened over the fundus uteri. The total exposure should be between 30 and 60 hours, spread over from 5 to 10 days, and the series should be repeated after six or eight weeks. The first effect noted is the checking of the metrorrhagia, and this is followed by a progressive decrease of the menorrhagia until the flow becomes normal, or sometimes ceases altogether. If any leucorrhœa exist this, too, is much diminished in amount, and not infrequently completely disappears.

Cases of *obstinate leucorrhœa* and *vaginal polypi* have been treated with complete success.

Nævi.

Flat Superficial Nævi, Capillary Nævi, "Port Wine Stains."—Before expressing an opinion as to the possibility of radium treatment effecting an improvement in any particular instance, it is advisable to subject the lesion to diascopy. If blanching is readily effected by gentle pressure the result of the treatment will probably be satisfactory; but if it be found impossible to produce blanching except by great pressure it is unlikely that radium can do much for the condition. The best results can be looked for when the nævus is quite superficial and shows no tendency to infiltration. If much infiltration exist the treatment will have to be much more vigorous, and a destructive reaction of slight degree produced. A smooth, supple, and white scar will be left.

Cavernous nævi.—These do excellently under radium, especially when of such shape that "cross-fire" radiation is possible. Half-strength applicators screened with 1/10 mm. of lead should be employed, and the exposure should be from one to three hours' duration, spread over three successive days. Little or no surface reaction is produced by this method of treatment, and the nævus shrinks gradually and steadily. If on palpation the presence of a pulsating vessel is appreciable, the case is not likely to prove completely successful unless the vessel first be ligated.

Warts and papillomata yield readily to exposures, with half-strength apparatus unscreened, of from 30 minutes to two hours' duration, according to the size and thickness of the lesion. The reaction is but slight and the resultant scar scarcely noticeable.

Tuberculosis.

Tuberculosis of glands.—In cases in which surgical measures have been declined for cosmetic reasons radium often proves of considerable value, either when used alone or as an adjunct to vaccine treatment. Heavily screened exposures of 20 or more hours' duration should be resorted to and an effort made to secure "cross-fire" irradiation where practicable. If the glands be caseating, radium treatment is of very little use.

Lupus vulgaris.—As a routine treatment for this disease Finsen light is greatly to be preferred to radium, but where it fails to effect a cure or improvement radium sometimes proves of great use. Unscreened exposures of one or two hours' duration must be given and a destructive reaction produced. The resultant scar is usually firm, smooth, supple, and inconspicuous.

Spring Catarrh.

In this condition the employment of radium is strongly to be advocated, as it will sometimes cure the most intractable cases. Personal idiosyncrasy is, however, a very important

consideration, and it is essential to proceed with great caution, giving short unscreened exposures at intervals of a fortnight, and carefully noting the reaction. If the dosage be accurately adjusted the granulations on the orbital conjunctiva gradually disappear, there is no marked inflammation and no resultant scarring of the mucous membrane.

Skin Diseases.

Keloid.—This condition continues to give most excellent results when treated with radium, and a great improvement, if not complete cure, can be safely predicted when the condition is of recent origin and occurs in young subjects. In tender and painful keloids the anæsthetic effect of radium is generally very marked and appears early in the treatment. Half-strength applicators screened with 1 mm. of silver are almost always employed, and an exposure of from 18 to 30 hours spread over from three to five days, according to the size and thickness of the lesion, is given. This brings about a gradual absorption of the keloid unaccompanied by any surface irritation. If, however, time be of importance, or the keloid prove refractory, screening of $\frac{1}{2}$ mm. of silver or 1/10 mm. of lead may be employed, though the reaction is likely to be definite and accompanied by vesication.

Lupus Erythematosus.—In early cases of this disease, which have not been subjected to much other treatment, one or two exposures not exceeding an hour in duration with a half-strength apparatus, unscreened or screened with 1/100 mm. of aluminium, may suffice to bring about the disappearance of the lesion. Care should be taken to ensure that the applicator employed is sufficiently large to reach well beyond the borders of the patch treated.

Lichenification of the Skin.—Patches of lichenification almost invariably yield to one treatment of ten minutes' duration with a half-strength applicator, unscreened or screened with 1/100 mm. of aluminium. The attendant intolerable itching is often markedly alleviated within 60 hours of the exposure. Some very obstinate cases which have hitherto defied all the usual methods of treatment have responded most favourably to this procedure, the lesions have disappeared and have not recurred.

Pruritus.—The analgesic effect of radium is often of the greatest use in this disease, and short unscreened exposures frequently produce a degree of relief which is unattainable by any other measures. This is especially noticeable if the pruritus occur in association with a definite lesion such as leucoplakia or hyperkeratosis.

Angio-neurotic Edema.

Three patients suffering from this condition have received treatment during the past year. In one instance a cure has apparently been effected; in the other two considerable benefit has been obtained. In view of the comparative rarity of this malady and its intractability to most methods of treatment the particulars of all these cases are given. These notes will be well worth studying in the complete report by those who are interested in this condition.

Arthritis Deformans.

The daily administration of 250 c.c. of radium emanation solution of a strength of not less than 1 millicurie per litre to patients suffering from this obstinate, painful, and crippling disease is sometimes attended by very remarkable results. It is difficult to predict with certainty the degree of improvement likely to occur in any particular instance, but the cases which appear to derive most benefit are those in which the disease is of relatively short duration, and the changes are periarticular in type and multi-articular in distribution. The age of the patient also exerts some influence, those under 40 responding more quickly to the action of the emanation. Cases with a definite gouty history sometimes experience an acute exacerbation of all their symptoms within the first week or ten days of their treatment, but this disturbance is quite transient, and is usually followed by a distinct change for the better. Little or no improvement can be looked for in instances where cartilaginous or osseous changes are predominant, and the radium emanation solution is powerless to bring about the absorption of osteophytic growths or the loosening of bony ankylosis. When limitation of movement is due to periarticular fibrous thickening considerable increase of mobility often follows on the taking of the radium water, and enables patients to perform actions, such as feeding themselves, brushing their hair, shaving, &c., which they may have been powerless to do for some months or even years.

Other favourable effects of the treatment are that the muscular and articular pains are lessened or disappear, the grating of the joints on movement is not so marked, the muscles regain much of their lost tone, and the patient's general health is much improved. This is especially noticeable when the patients are suffering from anæmia, the hæmoglobin index being rapidly increased. The treatment must, however, be persisted in for quite a long time, and at least six weeks are likely to elapse before any change is noted. With the majority of patients the emanation solution produces a definite diuresis, and with a few it acts as a slight laxative, though free purgation has never been observed. Much research work has yet to be undertaken to enable an accurate opinion to be formed of the manner in which radium emanation solution produces these results, as its action appears to be a multiple and highly complex one, but the reinforcing of the body ferments, the increase of tissue oxidation, and the dissolving of uric acid are probably factors which contribute to its success.

Prophylactic Irradiation.

Since the opening of the Radium Institute in August, 1911, numerous patients who have undergone operation for malignant disease have received post-operative prophylactic irradiation. It would be exceedingly difficult, if not impossible, to make any statement as to the precise value of radium treatment in preventing or minimising the danger of recurrence, but as the majority of these patients had suffered from extensive, severe, and rapidly progressive malignant disease, and the operators had expressed grave doubts as to the probability of their remaining free from the disease for more than a few months, the relatively slight proportion of recurrences so far recorded (19 per cent.) does much to justify the routine adoption of post-operative irradiation. It should prove of especial service in those cases of malignant growth in which it has been found impossible to operate well beyond the appreciable area of the disease.

In conclusion, Mr. Hayward Pinch expresses his great indebtedness to his senior assistant, Dr. J. E. A. Lynham, for most valuable help in the compilation of this report. Dr. Lynham was solely responsible for the planning and carrying out of the treatment of many of the cases herein recorded.

RADIUM TREATMENT AT THE ROYAL INFIRMARY, EDINBURGH.

Dr. Dawson Turner's report on the work done in the radium department of the Royal Infirmary Edinburgh, during the year 1914 has just appeared, and is full of suggestive information.

There attended for radium treatment during the past year 63 patients; of these, 36 were in-patients and 27 were out-patients. Thirty-four of the patients suffered from, in all but one case, inoperable malignant disease, 23 of these from carcinoma and 11 from sarcoma. There were 12 cases of rodent ulcer, 6 of exophthalmic goitre, 2 of otosclerosis, 1 of middle-ear deafness, 1 of Paget's disease, 1 recurrent wen, 1 simple tumour, 1 nævus, 1 leucoplakia, 1 warty tumour, and 1 hypertrophied tonsils. Though a cure was not effected in any of the malignant cases, nor considering their advanced nature was it to be expected, yet in practically all of those who were treated more or less benefit was produced by the relief of pain, the cessation of discharges, the healing of ulcerated surfaces, the removal of local growths, and the prolongation of life. In some of the cases radium was used as a prophylactic after the surgical removal of a growth, and sufficient time has not yet elapsed to ascertain its effect. Remarkable results were produced in some of the malignant cases; thus an epitheliomatous growth was entirely removed, first from the posterior wall and then from the anterior wall of the vagina, so that not a trace of it remained; there has, however, been a recurrence which is being treated. In a rapidly growing periosteal sarcoma of the lower end of the femur in a boy aged 13 the application of radium caused the growth to shrink and to become dense, hard, and fibrous, so that whereas, to use the words of the surgeon, Mr. J. W. B. Hodsdon, it bled like an aneurysm on the first introduction of radium, two months later, on a second introduction, it scarcely bled at

all, and it was so hard and dense that it was only with difficulty that the radium could be inserted. This was an illustration of the well-known effect of radium in converting a sarcomatous growth into a fibrous one. Malignant disease of the buccal cavity, the pharynx, larynx, and posterior nares appears to be less amenable to radium, but this may be partly due to the difficulty of administering a sufficient dose in such positions.

The beneficial effect of radium in rodent ulcer is now well recognised. Of the 12 cases treated during the year, 9 were easily cured, the remaining 3 have not yet been long enough under treatment for the effect to be produced. In each case the cosmetic result leaves no room for improvement. In small superficial rodent ulcers a single application may be sufficient, but it is important in order to prevent a recurrence that the deeper parts as well as the superficial should be adequately treated. Several of the cases had previously received without sufficient benefit applications of carbonic snow or large doses of the X rays. Though this may render them, as the Radium Institute reports indicate, more refractory to radium, yet none of those treated during the past year have failed to yield to it.

In the six cases of exophthalmic goitre treated during the year radium was of undoubted benefit, in one case apparently bringing about a definite cure. Its action consists in producing a sclerosis of the thyroid gland following upon an obliterative endarteritis. As the treatment of this condition by radium was novel great care had to be exercised in the earlier cases by giving small doses and keeping careful observation of the patients. Larger doses, which more rapidly produce a beneficial effect, are now administered. A diminution in the exophthalmos and tachycardia are amongst the first results to be observed.

The following is a summary of the cases, excluding the rodent ulcers:—

1. An advanced case of sarcoma under the left eye, with abscesses and an opening into the antrum of Highmore. A dose of 2280 mg.h. was given with temporary benefit.

2. A case of recurrent epithelioma following lupus in a male aged 41, recommended by Mr. D. Wallace. Growth affecting the region beneath the right ear was removed by Mr. Wallace, healed well, except a small patch which healed after a dose of 240 mg.h. of radium. Five months later a recurrence below, into which three tubes of radium were inserted and removed after a dose of 5040 mg.h. Six weeks later Mr. H. Wade reported a great improvement, the growth having practically disappeared. A few weeks later a recurrence occurred above, and radium treatment was given up.

3. Sarcoma of the scapula in a female aged 29, recommended by Mr. A. Miles. Radium used prophylactically after surgical removal of the scapula and inserted anteriorly. A dose of 360 mg.h. only was given owing to the proximity of the subclavian vessels. Three weeks later a rapidly growing recurrence higher up, not where the radium had rested. Two tubes were inserted into the recurrence and a dose of 2520 mg.h. given. A peculiar feature of this case was that the temperature of the patient always fell, and remained down during the radium applications. The radium relieved the patient's pain, which had been constant, but the patient rapidly sank.

4. Recurrent scirrhus in a female aged 37, recommended by Mr. Miles. Breast removed in August, 1912. Some time afterwards a swelling began over the sternum. On admission on Feb. 3rd, 1914, there was a large swelling over the sternum, measuring 3 by 2½ inches, and projecting about 1½ inches. A tube was introduced into the growth and radium applied externally in different positions shielded by 1 mm. of silver. The dose amounted to 5270 mg.h. Six months later the growth had disappeared. Photographs had been taken before and after treatment. Two months later two recurrences, one to the right, one above. A dose of 5700 mg.h. was given, with the result that the swellings were markedly reduced. This patient has ceased to attend.

5. A recurrent carcinoma of the rectum in a female aged 27. An aluminium tube containing radium was placed in a rubber tube and attached to a twisted silver wire. This was introduced so as to lie against the ulceration, and a dose of 1080 mg.h. administered. Mr. Hodsdon considered that this treatment was beneficial; the induration became less and pain was diminished. The patient went home and has not since attended for more treatment.

6. A large epithelioma of the lower jaw unsuitable for radium treatment.

7. An epithelioma of the lower lip in a male aged 55, recommended by Mr. C. W. Cathcart. The diseased area was about the size of a filbert nut; there was a crack in it above, but the mucous membrane was not invaded. A dose of 400 mg.h. was administered. Dismissed three weeks later greatly improved. Told to return in three weeks, but did

not do so for many months, when the condition was so much worse that an operation had to be performed. The case was one which would probably have entirely yielded to radium had the treatment been persisted in.

8. Secondary metastatic sarcoma in a female aged 27, recommended by Professor Alexis Thomson. Eight days after the growth had been removed from the back of the neck a tube of radium was introduced into the wound and a dose of 960 mg.h. administered. A year later her family doctor, Dr. T. P. Gemmell, wrote to say that he had examined her and could find no hardness or swelling near the cicatrix, and that she had made a marvellous recovery after we had expected her cure impossible.

9. Epithelioma of the vaginal walls in a patient aged 40, recommended by Dr. A. H. F. Barbour. Duration some months. Pain and watery discharge. There was a raised warty growth over upper two-thirds of posterior vaginal wall, also in anterior fornix. Microscopic examination showed it to consist of a squamous-celled epithelioma. Operation inadvisable owing to risk of a rectal fistula. 15 mg. of radium protected by 1 mm. of silver were fastened into a speculum and introduced so as to be in contact with the warty growth. A dose of 384 mg.h. was given. Six weeks later the patch was smaller and there was less discharge. 25 mg. of radium in an aluminium tube were attached to a pad protected on the upper surface by lead foil and placed in contact with the growth. A dose of 1050 mg.h. was given. Some local peritonitis and lung trouble followed. In four months' time when the patient returned no trace of the disease could be found on the posterior vaginal wall, but there was a decided plaque-like growth on the anterior wall. 20 mg. of radium protected by silver, 1.3 mm. thick, were placed against the growth and left in, except for douching, for seven days; dose 3200 mg.h. Six weeks later the growth had disappeared except for a trace in the anterior fornix. Two months later she returned with a hard lump on the anterior wall. The growth was rapidly increasing. By the application of 30 mg. of radium in aluminium a dose of 5060 mg.h. was given. A month later she returned complaining of pelvic pain, rectal discomfort, and discharge. On examination under chloroform the posterior vaginal wall, where the original growth had been, was found to be thickened, indurated, and grey coloured. The anterior wall presented the same appearance. Immediately below the cervix was a growth of the size of a gooseberry. The pathologist reported that this showed very extensive necrosis, so that it was impossible to recognise what the original tissue was. The patient is being kept under observation.

10. A rapidly growing recurrent sarcoma of the right orbit, very vascular. A case of Dr. Sims. A dose of 1920 mg.h. was given, but the patient died a few days later with head symptoms.

11. A scirrhus of the left breast in a patient aged 75, recommended by Mr. F. M. Caird. There was a hard tumour with an ulcerating crack and the glands were involved. To relieve pain a dose of 120 mg.h. in aluminium was given to the crack. The pain was relieved and there was great local improvement. The patient ceased to attend.

12. A fibrosarcoma of the right side of the neck in a man aged 34, a patient of Mr. J. W. Struthers. Duration six years. Aching pain. Neck circumference 17½ inches. 20 mg. in aluminium inserted through an incision and a dose of 5400 mg.h. given. Six weeks later growth no smaller, but more movable; pain removed. A large, fresh, deep incision showed a softened area where the tube had lain. Microscopically there were areas of necrosis round the positions in which the radium had been. By means of another tube a dose of 3840 mg.h. was given. Considerable reaction with a discharging sinus followed. Four months later the growth was found to be much smaller and more movable. Patient has ceased to attend.

13. A myeloid sarcoma of enormous size of the side of the face and back of the head in a man aged 54, recommended by Mr. J. W. Dowden. As a palliative a dose of 3360 mg.h. was given.

14. Recurrent carcinoma recti in a female aged 54, recommended by Mr. Hodsdon. Previous operation a year ago. colotomy performed, rectum removed. Now a fistula into the vagina, constriction, tenderness, and pain. 20 mg. in aluminium introduced and a dose of 3840 mg.h. given. Considerable amelioration followed with relief of pain.

15. Recurrent scirrhus in a woman aged 47, a patient of Mr. Caird. As the disease was very extensive the patient was recommended for X ray treatment.

16. Recurrent carcinoma of bowel round a colostomy opening in a female aged 41, recommended by Mr. Cathcart. Diabetic. A tube was inserted into the growth, but ulcerated out in three days. The patient died with head symptoms.

17. Sarcoma of tonsils in a man aged 50, recommended by Dr. Logan Turner. Four months' duration. Could not open mouth much or swallow solids. An ulcerating mass chiefly on right side. 20 mg. in an aluminium capsule at the end of a rod were held for some eight hours a day by the patient

close to, but not actually touching the ulcer. After a dose of 1310 mg.h. the patient ceased to attend. No beneficial effect, except that the ulcer appeared to get cleaner, was observed.

18. Carcinoma of cervix and vagina, advanced ulcerating, in a female aged 49, recommended by Mr. N. T. Brewis. 20 mg. in aluminium and rubber were placed in contact with the growth, and a dose of 3500 mg.h. given. This removed the agonising pain from which the patient suffered, but she died within a week of the radium treatment.

19. Inoperable carcinoma of the floor of the mouth in a man aged 70, a patient of Mr. Miles. Case unsuitable for radium treatment.

20. A case of recurrent sarcoma of the femur in a female aged 23, recommended by Professor Thomson. After amputation above the knee-joint two tubes of radium were inserted and a prophylactic dose of 3360 mg.h. was given. Eight months later her medical man reported that she was going on very well indeed.

21. A recurrent scirrhus in a female aged 70, recommended by Mr. Scott Carmichael. The first operation 19 months earlier; steady pain since. Second operation, June 26th, 1914, when a lump was removed and a tube of radium inserted as a prophylactic. Dose 1440 mg.h., aluminium screen. On being asked to report herself in January, 1915, the patient wrote to say that she was too ill to attend.

22. A male suffering from a malignant enlargement of the cervical glands on both sides. Considered unsuitable for radium treatment.

23. Epithelioma of the upper lip, invading the mucous membrane, in a male aged 58, recommended by Dr. F. Porter. Taken to see Mr. Cathcart who advised an operation.

24. Epithelioma of the left tonsil of eight months' duration in a male aged 41, recommended by Mr. Cathcart. Cervical glands enlarged. 20 mg. of radium in a capsule were held by the patient against the affected area daily, screened by aluminium, until a dose of 1065 mg.h. had been given. Considerable sloughing followed, but no improvement of any consequence. Patient was referred back to Mr. Cathcart.

25. Recurrent epithelioma of the upper jaw in a male aged 46, recommended by Mr. Hodsdon. Two years ago first operation. Now a hard mass growing in a cavity above his dental plate. By means of some radium attached to the end of a wire which the patient held against the growth, a dose of 600 mg.h. was administered. Screen aluminium. The patient ceased to attend.

26. Advanced case of paraffin epithelioma of the right hand in a man aged 57, recommended by Dr. A. Steven. Patient being sent to Mr. H. Wade for advice an operation was suggested.

27. Recurrent periosteal sarcoma of the left knee in a male aged 23, recommended by Professor Thomson. Previous operation four years earlier. Now there is a swelling of the size of a small egg, which Professor Thomson excised, and at the same time inserted 20 mg. of radium in aluminium. A dose of 2880 mg.h. was administered. Six months later his medical attendant wrote to say that there was no recurrence and that the leg was regaining strength.

28. Periosteal sarcoma of the lower end of the femur in a boy aged 13. The parents refused operation. Duration five months; immobility, pain, and swelling. Greatest circumference of knee 13 inches. On Sept. 22nd, 1914, Mr. Hodsdon made an incision and inserted 30 mg., contained in two aluminium tubes, into the swelling. Blood gushed from the growth as though it were an aneurysm. Radium, shielded by silver 1 mm. in thickness, was also applied externally. The position of the internal tubes and of the external capsules was shifted from time to time. A total dose of 8760 mg. hours was given. The boy was sent home. In two months' time, when he returned, it was observed that the swelling had diminished in size, the pain had disappeared, the part was less tender, and he could move it more freely. It had been growing rapidly. By a fresh incision a tube was pushed down deeply so as to be in contact with the bone. The part incised scarcely bled at all, and the tissues had become hard and fibrous, making it difficult to introduce the tube. A dose of 3840 mg.h. was administered. The knee now became more swollen and tender and the temperature rose. It was evident that the contact of the radium tube with the diseased bone was setting up a severe reaction. The boy shortly afterwards returned home. Six months later his medical adviser wrote to say that the right lung was affected and that the patient was sinking. The knee remained *in statu quo*, but was discharging pus from the cavity in which the tube had lain. The radium appeared to have stopped the local growth, but had not prevented a metastasis.

29. A case of epithelioma following lupus erythematosus and excessive X ray treatment affecting the chin in a woman aged 67, recommended by Dr. F. Gardiner. Case unsuitable for radium treatment.

30. Case of epithelioma of the vulva in a patient aged 61, recommended by Dr. Barbour. Case unsuitable for radium treatment except after an operation.

31. Recurrent metastatic sarcoma of right side of the chest in a male aged 35, recommended by Sir Robert Philip. Case unsuitable for radium treatment.

32. Case of exophthalmic goitre in a female aged 28, recommended by Professor Lovell Gulland. Swelling of neck began in August, 1913, but the patient had been getting weaker before then. On admission, tachycardia (140), marked exophthalmos, tremulous, sweating, glycosuria. In March, 1914, patient was given, by external application through silver 1 mm. thick, a dose of 360 mg.h. to the thyroid. On April 24th she returned much better. Gave her a dose of 400 mg.h. On Sept. 14th the pulse was 80, exophthalmos less, better in every way. Gave her a dose of 540 mg.h. On Oct. 17th gave her a dose of 400 mg.h. On Dec. 23rd she returned practically restored to health; pulse 70, no exophthalmos, thyroid cannot be palpated. Professor Gulland writes in reference to this and another case: "This case had a considerable number of applications at long intervals, and has immensely benefited thereby. She has, in fact, within a year returned to normal—an unusually good result. The second case has had only one application and naturally did not do so well, though she also greatly improved."

33. Exophthalmic goitre in a female aged 27, recommended by Dr. F. D. Boyd. Duration three years. Breathlessness, nervousness, tremor of hands, pulse 120, thyroid enlarged, exophthalmos slight. This patient was given a total dose of 1750 mg.h., administered as in the last case. On Jan. 15th, 1915, Dr. Boyd wrote: "The patient seems to have benefited very much from radium, and I think a second dose would be very desirable."

34. Exophthalmic goitre in a woman aged 32, recommended by Professor Gulland. A mild case of three months' duration. Slight exophthalmos, weakness, nervousness, palpitation, oedema, thyroid slightly enlarged. Medicinal treatment so far unavailing. A dose of 600 mg.h. administered externally, as in the last case. This is the second patient referred to in Professor Gulland's letter, in which he described her as being greatly improved. The other three cases of exophthalmic goitre were only given treatment at the end of October, and they have not yet returned to report themselves.

Two cases of otosclerosis and one of middle-ear deafness were treated with radium during the year. They are as follows:—

35. A female aged 52, recommended by Dr. J. S. Fraser. Deaf for 25 years and regarded as hopeless. Dr. Fraser writes: "The raised voice before treatment could only be heard at 6 inches in both ears. After six applications of radium (dose 106 mg.h.) there was no improvement, and the patient stated that the noises had been worse. The raised voice was only heard at 4 inches in the ear which had been treated. This was a case of advanced otosclerosis."

36. Case of early otosclerosis in a female aged 22, recommended by Dr. Fraser, who writes regarding her as follows: "She had been slightly deaf since childhood. Before radium treatment the low voice was heard at 1 foot in the right ear. Radium treatment was commenced in February, 1914. I saw the patient again in May, after she had had a dose of 125 mg.h. of radium, and was suffering from a considerable amount of dermatitis of the external meatus on the right side, probably due to the radium. I saw her for the last time on Nov. 6th, 1914, and found that the right meatus had quite healed. The hearing was about the same as before—viz., low voice at 1 foot."

37. Case of middle-ear deafness in a female aged 45, recommended by Dr. Fraser, who writes as follows: "Patient had been deaf for ten months and complained of noises in the ears. Before radium treatment the raised voice was heard at 1 foot by the left ear. After a dose of 55 mg.h. she stated that the noises were not so bad as before. The voice was heard at about 18 inches by the left ear. I do not think that the difference between 1 foot (before treatment) and 18 inches (after treatment) is of any importance, as a small difference in hearing like this might easily be due to the room being more quiet or to the voice used being rather louder. In conclusion, I am afraid we must report that these cases of chronic progressive middle-ear deafness have not benefited from radium treatment, but this was only to be expected."

38. Case of naevus of the scalp in an infant aged 1 year, recommended by Mr. D. Cotterill. Had been treated by injections of carbolic acid and glycerine. There was a scab in the centre and a raised red ring around. A dose of 115 mg.h. was sufficient to cure this condition.

39. Paget's disease in a female aged 72, recommended by Mr. Miles. To right of nipple was a well-defined crescentic area, red, slightly elevated, and hard. Glands not palpable. Nipple normal. A dose of 1200 mg.h. was administered, guarded by silver and cork so as to spread the effect. The patient has not reappeared for treatment.

40. Warty tumour in a girl aged 18, recommended by Dr. G. Ogilvie. Duration about two years. Has had nitric acid and other applications without benefit. On the left cheek is a wart the size of a threepenny-piece, considerably elevated above the surface. Radium treatment begun on March 24th, 1914, and a dose of 58 mg.h. administered. On June 2nd, 1914, the wart was found to have disappeared and the skin to be practically normal.

41. Leukoplakia. As this case was only admitted for treatment in December, 1914, it is too early to make any report upon

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned have been granted temporary commissions as Surgeons in His Majesty's Fleet: William Bell, J. Westwood, Samuel F. Abbott, Edgar William Todd, Clive Nelson Pitt, and Benjamin Lewitt.

The following appointments have been notified:—F. H. Rees to the *Vivid*, additional, for Plymouth Hospital; S. Worthington and H. G. Moser to the *Victory*, additional, for Haslar Hospital; and R. W. Townley to hospital ship *China*.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeons: T. D. McEwan and E. J. Steegman, both to the *Pembroke*, additional, for disposal.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Alfred Blenkinsop, on appointment as Assistant Director-General, Army Medical Service, to be supernumerary (dated Oct. 29th).

The undermentioned to be temporary Captains:—Dated Feb. 24th: Temporary Lieutenants John Francis O'Malley and Lanyon Edward Owen.

Lieutenant-Colonel William E. Berryman is retained on the active list under Article 120, Royal Warrant for Pay and Promotion, and to be supernumerary (dated Feb. 22nd).

Captain Claude M. Rigby is seconded for service on the staff of the Governor of Bombay (dated Jan. 5th).

Laurence MacLagan-Wedderburn to be temporary Captain (dated Feb. 5th).

The undermentioned to be temporary Lieutenants:—Dated Jan. 23rd: Norman Black. Dated Jan. 25th: Alexander Fleming Wilkie Millar. Dated Jan. 28th: James Patrick Lavery, Walker Stewart Lindsay, Josiah Russell Turner, George Davidson, and George Theodore Cregan. Dated Jan. 29th: John Adam Gib Burton. Dated Jan. 30th: Alfred Castle Warren, John Robert McGilvray, Hubert Samuel Stockton, Frank Reginald Featherstone, Charles de Chanval Peller, Vivian Percival Foote, and Delbert Evans. Dated Feb. 1st: Frederick Patrick Walsh, Geoffrey Fildes, Henry Wardel Snarey Wright, Edmund Claud Malden, William Kenneth Armstrong Richards, Charles Roche, John Wesley Gilbert, Sidney Howard Browning, Kenneth Playfair, James Henry Bampton, Frederick Rosenberg Harris, Thomas Arnold Watson, Thomas Louis Enright, Henry Holman Weekes, John Warnock Bingham, Arthur Harold Wilson, Arthur Geoffrey Pattison Hardwick, William Joseph Burns Selkirk, Robert Murray Fraser, John Reid Forde, Frank Sholl Scott, Herbert Temple Lukyn-Williams, William Deanburn Dunlop, Thomas Howard Frederick Roberts, David Wilson, George William Blomfield James, Francis Joseph Henry, Charles O'Brien, Kenneth Duncan Cameron Macrae, Bernard Rayne Parmiter, James Wilfred McKinney, Ernest Tawse, James David Forrester, Graham Smith, John Perrin Brown, Arthur Robertson Wightman, Reginald Arthur Morrell, Harold Axel Haig, Norman Duggan, Sidney Bertram Radley, Douglas Erith Derry, Lomond Charles Dillon-Kelly, Cecil Francis Dillon-Kelly, Eugene Patrick Leahy, Francis Percival Halkyard, Robert Tindall, Thomas MacKnight Watt, Robert Henry Liscombe, Frank Lee Cleland, Archibald Fullerton, Ernest Eugene Herga, William Anderson Coats, Theodore Essex Roberts, Richard Robins Armstrong, and Alexander Nelson Craig. Dated Feb. 2nd: Malcolm Gross, Arthur Wandersford Comber, and William Anderson. Dated Feb. 3rd: Adrian St. Johnston and Duncan Metcalfe Morrison. Dated Feb. 4th: Claude Emery Freeman, Herbert Smith, and William Barwise Sanders. David John Jones, and Charles Herbert Gouldsmith France. Dated Feb. 5th: Horace James Gater, George Galen Bartholomew, and Franke Chamberlain Hart-Smith. Dated Feb. 6th: Walter Randall Knightley, Philip Maynard Heath, Sydney Boyd Faulkner, Archibald Hamilton Jacob, Henry Beveridge Smith, Joseph Caton-Shelmerdine, Edward Longueville Mansel, Harold Charles Harrison, and Alfred Edward Seller. Dated Feb. 7th: Harold William Wilson, Thomas Pearson Herriot, Archibald Cowe, John Edgar Davies, John Campbell Neil, John Kelly, William MacLeod, Francis Edgar Sprawson, Oliver Beakley Pratt, Tom Watson Wadsworth, Edward Henry Fennessy, Stanley Thorpe Lewis, Drevor Frederick Acton Neilson, and Leonard Hankinson Terry. Dated Feb. 8th: William Henry Croly, Thomas Edwin Hammond, Griffith Llewellyn Jones, Percy Lytton Tempest Bennett, John Hamilton Boag, Charles George Gordon Keane, William Francis MacAlevey, Kenneth Montague Nelson, Arthur Henry Towers, Henry Strawson Turner, Philip Pennefather Warren, Patrick William White, Arthur James Bruce Leckie, Hugh Gwilym Morris, Maxwell Ramsay, and Charles Rowley Nicholson. Dated Feb. 10th: Abram Leach, Andrew Richmond Douglas, Francis Percy Evers, Arthur Loudoun Taylor, William Campbell, Joseph Marmion, Laurence Unthank Geraty,

George Leggat, Christopher Robson Dudgeon, Frank Hamersley Woods, Llewellyn McIntyre Weeks, John Macintyre, Harold Esmond Arnison Boldero, Cedric Sydney Lane Roberts, Henry Albert Gillespie, Henry Carson Duffy, Lennox Ross Broster, James Patrick Fitzpatrick, Louis Thomas Eden, Eric Stewart Marshall, James Ingram Pirie Wilson, Henry George Frean, and Patrick Ashe.

OVERSEA CONTINGENTS: CANADA.

Colonel Guy C. Jones, Director-General of Medical Services, Canada, to be temporary Surgeon-General (dated Jan. 26th).

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Captain George H. Usmar resigns his commission. Captain Thomas Douglas Inch, from the Unattached List, Territorial Force, to be Lieutenant.

The undermentioned Lieutenants are confirmed in their rank:—Frederick Sanders, George S. Pirie, Howell M. Williams, William D. Anderton, Edwin J. Bradley, Frank Oppenheimer, James W. Wood, and George M. Scott.

The undermentioned to be Lieutenants (on probation):—Edward Waller Mann, ex-Cadet of the Officers Training Corps, and William Theodore Hare.

TERRITORIAL FORCE.

Army Medical Services.

Colonel de Burgh Birch, C.B., Retired List Territorial Force, to be Assistant Director of Medical Services, West Riding Reserve Division.

Royal Army Medical Corps.

1st South Midland Mounted Brigade Field Ambulance: Captain Douglas M. Spring to be Major (temporary).

4th London Field Ambulance: To be Lieutenants: Leslie Price Harris and George Brentnall Pritchard.

3rd South Midland Field Ambulance: Major Bertram M. H. Rogers to be Lieutenant-Colonel (temporary).

2nd London Casualty Clearing Station: Captain Claude H. S. Frankau, from the 4th London General Hospital, to be Captain.

2nd Lowland Field Ambulance: James Angus to be Lieutenant.

3rd North Midland Field Ambulance: To be Lieutenants: William Batten Williams and George Fanning Denning.

3rd West Riding Field Ambulance: Surgeon-Captain William Smith Kerr, from the 4th (Hullamshire) Battalion York and Lancaster Regiment, to be Captain.

1st London (City of London) Sanitary Company: Constant Wells Ponder to be Lieutenant.

2nd South Midland Mounted Brigade Field Ambulance: Alfred Goodman Levy to be Lieutenant.

2nd East Anglian Field Ambulance: Edmund Albert Goulden to be Lieutenant.

2nd London (City of London) General Hospital: Captain Charles A. Lees to be Major on the permanent personnel.

3rd Southern General Hospital: Fielding Clarke to be Captain, whose services will be available on mobilisation.

1st London (City of London) Field Ambulance: Roger Papillon Stewart to be Lieutenant.

1st East Anglian Field Ambulance: Captain William James Hoyten, from Attached to Units other than Medical Units, to be Captain.

2nd Western General Hospital: Thomas Pomfret Kilner to be Lieutenant.

Attached to Units other than Medical Units.—Surgeon-Major Bertram Addenbrooke, from 7th Battalion, The Worcestershire Regiment, to be Major. To be Captains: Honorary Captain Arthur Ricketts, C.M.G., Lieutenant Charles D. Mathias (temporary), and Captain Francis Rowland (from the 6th London Field Ambulance). To be Lieutenants: Hugh Arthur Sandford, Ivan William McKinnon, Ernest Osborne, Frederick George Vicars, Kenneth John Taylor Keer, John James Egerton Biggs (late Captain 7th (Cyclist) Battalion, the Welsh Regiment), and Henry Frederick John Graves. Captain Ellerington Reed Turner resigns his commission on account of ill-health.

COLONIAL MEDICAL SERVICES.

West African Medical Staff.—The death is reported of Dr. J. Atkinson. The following have been transferred on promotion: Mr. H. B. S. Montgomery, Provincial Medical Officer, Gold Coast, to Nigeria as Deputy Principal Medical Officer; Dr. J. W. Collett, Senior Medical Officer, Sierra Leone, to Nigeria as Provincial Medical Officer; Mr. D. Burrows, Senior Medical Officer, Nigeria, to Sierra Leone as Provincial Medical Officer; Mr. E. C. Adams, Medical Officer, Nigeria, to the Gold Coast as Senior Medical Officer; Mr. T. F. G. Mayer, Medical Officer, Gambia, to Sierra Leone as Senior Medical Officer; and Mr. F. J. A. Beringer, Medical Officer, Gold Coast, to Sierra Leone as Sanitary Officer. Dr. E. W. Graham, Senior Medical Officer, Gold Coast, has been promoted to be Provincial Medical Officer. Mr. T. B.

Adam, Captain J. B. Bate, R.A.M.C. (T.F.), Mr. G. Hungerford, Dr. G. R. Twomey, Dr. R. W. Gray, Mr. E. H. Tipper, and Mr. H. G. McKinney, Medical Officers, Nigeria, have been promoted to be Senior Medical Officers. Dr. F. S. Harper, Mr. C. D. Ralph, and Dr. C. V. Le Fanu, Medical Officers, Gold Coast, have been promoted to be Senior Medical Officers. Mr. C. H. Allan, Medical Officer, Sierra Leone, has been promoted to be Senior Medical Officer. Mr. A. C. Lorena, Medical Officer, Gold Coast, has been promoted to be Sanitary Officer. *Retirements*: Mr. M. F. Ellis (on pension), and Dr. B. Knowles. *New appointment*: Dr. E. B. Bate (Gambia). The services of the following officers have been placed at the disposal of the War Office: Captain J. B. Bate, R.A.M.C. (T.F.); temporary Lieutenant D. T. Birt, R.A.M.C.; and temporary Lieutenant G. J. W. Keigwin, R.A.M.C. The services of the following officers have been placed at the disposal of the Admiralty: Temporary Surgeon M. B. Hay, R.N.; and temporary Surgeon J. C. Watt, R.N.

Other Colonies and Protectorates.—Dr. C. M. Rolston has been selected for appointment as a Supernumerary Medical Officer in the Leeward Islands; Dr. J. H. Rankin has been selected for appointment as temporary Medical Officer in St. Lucia; Dr. A. MacDonald, medical officer of health, Kingston, Jamaica, has been selected for appointment as Medical Officer in charge of ankylostomiasis work in Grenada; Dr. F. T. Auden has been selected for appointment as District Commissioner and Medical Officer at Caicos in the Turks and Caicos Islands; Mr. J. G. Lessey has been selected for appointment as Resident Surgeon of the Colony Hospital, Grenada; and Dr. N. H. Bolton has been selected for appointment as a Medical Officer, Zanzibar.

DEATHS IN THE SERVICES.

Staff-Surgeon George Joseph Fogerty, late R.N., recently at Limerick. He joined the service in 1876, was surgeon of the *Carysfort* during the Egyptian War of 1882, and during the naval and military operations near Suakin in 1884 (medal and Suakin clasp and the Khedive's bronze star). He retired in 1898.

Surgeon Charles Harper, late R.N., at Bath on Feb. 16th, aged 87 years. In 1850 he was appointed surgeon to H.M.S. *Phaeton*, and subsequently served on the *Hogue* and the *Impregnable*. Later he became surgeon on the *Exmouth*, the flagship of Admiral Sir Michael Seymour, and served throughout the Baltic Campaign (medal and mentioned in despatches). In 1856 he was appointed to the Royal Hospital, Stonehouse.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last census, 8710 births and 7191 deaths were registered during the week ended Saturday, Feb. 20th. The annual rate of mortality in these towns, which had been 19.2, 20.1, and 18.9 per 1000 in the three preceding weeks, rose in the week under notice to 20.7 per 1000 of their aggregate population, estimated at 18,134,239 persons at the middle of 1914. During the first seven weeks of the current quarter the mean annual death-rate in these towns averaged 19.3, against 20.0 per 1000 in London. The annual death-rate last week ranged from 9.4 in Leyton, 9.9 in Swindon, 12.0 in Ilford, 12.2 in Acton, and 12.5 in Edmonton, to 29.4 in Merthyr Tydfil, 30.7 in Newcastle-on-Tyne, 35.6 in Southport, 37.7 in Darlington, and 39.8 in Cambridge.

The 7191 deaths from all causes were 633 in excess of the number in the previous week, and included 607 which were referred to the principal epidemic diseases, against 513 and 511 in the two preceding weeks. Of these 607 deaths, 263 resulted from measles, 135 from whooping-cough, 80 from diphtheria, 80 from infantile diarrhoeal diseases, 32 from scarlet fever, and 17 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1.7, or 0.2 per 1000 higher than in the previous week. The deaths attributed to measles, which had been 191, 210, and 207 in the three preceding weeks, rose to 263 last week, and caused the highest annual death-rates of 2.9 in Plymouth and in Newcastle-on-Tyne, 3.4 in Northampton, 3.7 in Merthyr Tydfil, 3.8 in Tottenham, 4.4 in Gateshead, 4.7 in St. Helens, 7.0 in Darlington, and 8.1 in Cambridge. The deaths referred to whooping-cough, which had increased from 76 to 125 in the five preceding weeks, further rose to 135 last week; the highest recorded death-rates from this disease were 1.2 in Reading and in Blackburn, 1.6 in Brighton, 1.7 in Wigan, 2.0 in Carlisle, 2.1 in Gloucester, 3.7 in Merthyr Tydfil, and 5.0 in Bootle. The fatal cases of diphtheria, which had declined from 83 to 66 in the four preceding weeks, rose to 80 last week, and included 17 in London, 6 in Birmingham, 4 in Southampton, and 3 each in

Portsmouth, Stoke-on-Trent, Liverpool, Bolton, Manchester, Salford, Preston, Middlesbrough, and Newcastle-on-Tyne. The deaths of infants (under 2 years) attributed to diarrhoea and enteritis, which had been 73, 68, and 70 in the three preceding weeks, further rose to 80 last week, of which 20 were registered in London, 8 in Birmingham, 6 in Liverpool, and 4 each in Wigan and Oldham. The deaths referred to scarlet fever, which had been 31, 22, and 27 in the three preceding weeks, further rose to 32 last week, and included 10 in London, 3 in Newcastle-on-Tyne, and 2 each in Ipswich, Bristol, and Preston. The fatal cases of enteric fever, which had been 12, 17, and 16 in the three preceding weeks, were 17 last week, of which 4 occurred in London and 2 in Birmingham.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 5035 to 3299 in the 12 preceding weeks, had further decreased to 3165 on Saturday last; 295 new cases were admitted during the week, against 326, 365, and 368 in the three preceding weeks. These hospitals also contained on Saturday last 1616 cases of diphtheria, 231 of measles, 65 of enteric fever, 8 of whooping-cough, and 5 of small-pox. The 1802 deaths from all causes in London were 106 in excess of the number in the previous week, and corresponded to an annual death-rate of 20.8 per 1000. The deaths referred to diseases of the respiratory system, which had been 450, 497, and 455 in the three preceding weeks, rose to 459 in the week under notice, and were 214 in excess of the number recorded in the corresponding week of last year.

Of the 7191 deaths from all causes in the 96 towns 203 resulted from different forms of violence and 501 were the subject of coroners' inquests, while 1937 occurred in public institutions. The causes of 45, or 0.6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Manchester, Leeds, Bristol, Bradford, and in 52 other smaller towns. Of the 45 uncertified causes of death 7 were registered in Birmingham, 4 in Liverpool, 3 in St. Helens, and 2 each in Warrington, Bury, Huddersfield, Sheffield, Hull, Darlington, South Shields, Gateshead, and Carlisle.

HEALTH OF SCOTCH TOWNS.

IN the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1164 births and 1024 deaths were registered during the week ended Saturday, Feb. 20th. The annual rate of mortality in these towns, which had been 22.4, 24.1, and 23.1 per 1000 in the three preceding weeks, fell to 22.8 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual death-rate in these towns averaged 23.1, against 19.3 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 8.9 in Paisley, 10.5 in Clydebank, and 15.1 in Motherwell, to 29.2 in Leith, 32.6 in Ayr, and 37.1 in Dundee.

The 1024 deaths from all causes were 13 fewer than the number in the previous week, and included 139 which were referred to the principal epidemic diseases, against 147 and 122 in the two preceding weeks. Of these 139 deaths, 97 resulted from whooping-cough, 13 from measles, 10 each from scarlet fever and infantile diarrhoeal diseases, 8 from diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 3.1, against 1.7 per 1000 in the large English towns. The deaths attributed to whooping-cough, which had been 82, 86, and 81 in the three preceding weeks, rose to 97 last week, and included 50 in Glasgow, 27 in Dundee, 4 each in Edinburgh and Motherwell, and 3 each in Greenock and Kilmarnock. The deaths referred to measles, which had been 6, 13, and 11 in the three preceding weeks, were 13 last week, and comprised 6 each in Glasgow and Dundee, and 1 in Edinburgh. The fatal cases of scarlet fever, which had been 12, 17, and 8 in the three preceding weeks, rose to 10 last week, and comprised 5 in Aberdeen, 4 in Glasgow, and 1 in Falkirk. The deaths of infants (under 2 years) attributed to diarrhoea and enteritis, which had been 15, 16, and 14 in the three preceding weeks, further declined to 10 last week, and included 3 in Glasgow and 2 each in Edinburgh and Aberdeen. The deaths referred to diphtheria, which had been 10, 13, and 6 in the three preceding weeks, rose to 8 last week, of which 4 occurred in Glasgow. The fatal case of enteric fever was registered in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 272, 302, and 278 in the three preceding weeks, further fell to 265 in the week under notice, but were 122 in excess of the number recorded in the corresponding week of last year; 26 deaths resulted from different forms of violence, against 36 and 35 in the two preceding weeks.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JANUARY, 1915.

* Including membranous croup. † The death-rates are corrected for variations in sex and age constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,212,380 persons at the middle of this year, 639 births and 617 deaths were registered during the week ended Saturday, Feb. 20th. The annual rate of mortality in these towns, which had increased from 24.0 to 26.5 per 1000 in the four preceding weeks, was again 26.5 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual death-rate in these towns averaged 25.5, against corresponding rates of 19.3 and 23.1 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 31.5 in Dublin (against 20.8 in London and 22.3 in Glasgow), 23.3 in Belfast, 31.3 in Cork, 27.8 in Londonderry, 19.0 in Limerick, and 34.2 in Waterford, while in the 21 smaller towns the mean death-rate was 21.7 per 1000.

The 617 deaths from all causes were 2 in excess of the number in the previous week, and included 36 which were referred to the principal epidemic diseases, against numbers increasing from 32 to 44 in the three preceding weeks. Of these 36 deaths, 12 resulted from whooping-cough, 10 from infantile diarrhoeal diseases, 6 from measles, 4 each from scarlet fever and diphtheria, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 1.5, against corresponding rates of 1.7 and 3.1 per 1000 in the English and Scotch towns respectively. The deaths attributed to whooping-cough, which had increased from 9 to 17 in the four preceding weeks fell to 12 last week, and comprised 6 in Dublin and 3 each in Belfast and Cork. The deaths of infants (under 2 years) referred to diarrhoea and enteritis, which had increased from 4 to 13 in the four preceding weeks, fell to 10 last week, and included 4 each in Dublin and Belfast. The fatal cases of measles, which had been 4, 6, and 5 in the three preceding weeks, were 6 last week, of which 5 occurred in Belfast and 1 in Coleraine. The 4 deaths attributed to scarlet fever, of which 2 were registered in Waterford, were slightly below the average in the earlier weeks of the quarter. Of the 4 deaths referred to diphtheria 3 occurred in Dublin and 1 in Wexford.

The deaths referred to diseases of the respiratory system, which had increased from 137 to 182 in the four preceding weeks, fell to 168 in the week under notice. Of the 617 deaths from all causes, 191, or 31 per cent., occurred in public institutions, and 18 resulted from different forms of violence. The causes of 31, or 5.0 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the English towns the proportion of uncertified causes did not exceed 0.6 per cent.

VITAL STATISTICS OF LONDON DURING JANUARY, 1915.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the 10 diseases specified in the table was equal to an annual rate of 7.4 per 1000 of the population, estimated at 4,516,612 persons in the middle of 1914¹; in the three preceding months the rates were 14.0, 12.5, and 9.2 per 1000 respectively. The lowest rates last month were recorded in Kensington, Chelsea, Hampstead, Holborn, and Poplar; and the highest rates in Stoke Newington, Bethnal Green, Stepney, Greenwich, and Woolwich. The prevalence of scarlet fever showed a marked decrease from that recorded in other recent months; the greatest proportional prevalence was recorded last month in Fulham, Stoke Newington, Stepney, Greenwich, and Woolwich. The Metropolitan Asylums Hospitals contained 3609 scarlet fever patients at the end of last month, against 4561, 4956, and 4431 at the end of the three preceding months; the weekly admissions averaged 317, against 618, 661, and 445 in the three preceding months. Diphtheria showed a slight decline from the number in the preceding month; this disease was proportionally most prevalent in Stoke Newington, St. Pancras, the City of London, Shoreditch, Bethnal Green, Stepney, and Lewisham. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1489, 1630, and 1663 at the end of the three preceding months, had declined again to 1621 at the end of last month; the weekly admissions averaged 160, against 213, 247, and 177 in the three preceding months. Enteric fever also was much less prevalent than it had been in other recent months; the greatest proportional prevalence of this disease last month

was recorded in Fulham, Bethnal Green, Lambeth, Deptford, and Woolwich. There were 50 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 65, 63, and 68 at the end of the three preceding months; the weekly admissions averaged 6, against 11, 8, and 10 in the three preceding months. Erysipelas was proportionally most prevalent in Hammersmith, Islington, Hackney, Shoreditch, Bethnal Green, Stepney, Southwark, and Greenwich. The 39 cases of puerperal fever notified during the month included 6 in Fulham, 4 in Stepney, and 3 each in Shoreditch, Lambeth, and Camberwell. The 26 cases of cerebro-spinal meningitis included 3 each in Paddington, Islington, and Woolwich, and 2 each in the City of Westminster, Bethnal Green, Poplar, and Greenwich; of the 4 cases of poliomyelitis 2 belonged to Lambeth and 1 each to Stepney and Poplar.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex and age constitution of the populations of the several boroughs. During the four weeks ending Jan. 30th the deaths of 6792 London residents were registered, equal to an annual rate of 19.6 per 1000; in the three preceding months the rates were 14.1, 14.6, and 16.7 per 1000 respectively. The death-rates last month ranged from 14.2 in Hampstead, 15.4 in Camberwell and in Lewisham, 15.8 in Wandsworth, and 17.3 in Battersea, to 22.2 in the City of London, 23.2 in Poplar, 23.3 in St. Pancras, 23.5 in Finsbury, 23.6 in Bermondsey, and 24.1 in Southwark. The 6792 deaths from all causes included 174 from measles, 26 from scarlet fever, 58 from diphtheria, 80 from whooping-cough, 9 from enteric fever, and 73 from diarrhoea and enteritis among children under 2 years of age. No death from any of these diseases was recorded last month in Chelsea or in the City of London; among the other boroughs they caused the lowest rates in the City of Westminster, St. Marylebone, Kensington, Stoke Newington, and Lewisham; and the highest rates in Hammersmith, Hackney, Finsbury, Bethnal Green, Southwark, Bermondsey, and Battersea. The 174 fatal cases of measles were 32 in excess of the corrected average number, the greatest proportional mortality from this cause being recorded in Hammersmith, Hackney, Southwark, Bermondsey, and Battersea. The 26 deaths from scarlet fever were 11 above the corrected average, and included 4 in Deptford and 2 each in Kensington, St. Pancras, Stepney, Poplar, Bermondsey, and Wandsworth. The 58 fatal cases of diphtheria were 11 above the corrected average; this disease was proportionally most fatal in Hammersmith, St. Pancras, Bethnal Green, Greenwich, and Woolwich. The 80 deaths from whooping-cough were 8 below the corrected average number; the highest death-rates from this disease last month were recorded in Hammersmith, Hampstead, Holborn, Finsbury, Bermondsey, and Greenwich. The 9 fatal cases of enteric fever were 5 below the average, and belonged respectively to Paddington, Fulham, the City of Westminster, Bethnal Green, Poplar, Lambeth, Battersea, Lewisham, and Woolwich. The mortality from diarrhoea and enteritis among children under 2 years of age was proportionally greatest in Hammersmith, Fulham, Hackney, Finsbury, Shoreditch, and Bethnal Green. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases, excluding diarrhoea, was 13.4 per cent. above the average.

BRISTOL MEDICAL MISSIONARY SOCIETY.—The annual meeting of subscribers to this society was held last week. The medical report stated that during 1914 9636 patients had been treated, and 2263 cases had been attended at their own homes. The financial statement showed a small unfavourable balance.

DUBLIN LECTURESHIP IN OPHTHALMOLOGY.—The Board of Trinity College, Dublin, as announced in these columns last week, is about to appoint a lecturer in ophthalmology. The terms of appointment are somewhat novel. The lecturer is to engage to devote himself to the special study of some branch of ophthalmology for a period of the term of his appointment. He is to give evidence of having studied by delivering one or more lectures embodying the result of his researches to the medical men and medical students of Dublin. The annual value of the lectureship is £150, and the lecturer may be re-elected year by year to a maximum of five years. The funds for the purpose were left by the late Mr. R. J. Montgomery, a Dublin oculist.

¹ For the middle of 1915 it is proposed to base estimates of population upon the returns of births, deaths, and migration. Until these are available the estimates for 1914 will be used in the Registrar-General's returns.

Correspondence.

"Audi alteram partem."

URGENCY CASES HOSPITAL FOR FRANCE.

To the Editor of THE LANCET.

SIR,—We hope that you will let us put before your readers the following statement. The arrangements for the Urgency Cases Hospital are so nearly complete that the committee hope to be able to send out the hospital early in March. Its services have been accepted by the French Ministry of War, and the arrangements made have received the approval of the Anglo-French Hospitals Committee. The French military authorities have promised to provide a suitable building or buildings for 60 patients and for the staff. It will be the special work of this hospital to treat severe urgent surgical cases among the French wounded on the lines of communication between the firing line and the base hospitals. The burden already put on French army surgeons in attendance on such cases is wellnigh overwhelming, and it is likely to become not lighter but heavier. The Urgency Cases Hospital, placed some 15 miles behind the firing line, will greatly relieve the present strain on the care of the severely wounded among the French army.

The hospital staff has been appointed as follows:—Consulting surgeon: Major A. W. Mayo-Robson, C.V.O. (who has been kindly permitted by the War Office to go out with the hospital for the first month of its work). Surgeons: Dr. J. A. Cairns Forsyth and Dr. K. E. Leveson Gower Gunn. Assistant surgeons: Dr. A. S. Robinson and Dr. W. H. Ogilvie. Anaesthetist: Dr. R. W. W. Vaughan. Radiographer and electrician: Mr. J. G. Everitt. Secretary: Mr. Harry Eyres (late Consul General at Constantinople). Nursing and domestic staff:—Matron: Miss Curtis (late superintendent, Hammersmith District Nursing Association). 17 nurses, quartermaster, and 14 orderlies; superintendent of laundry and one assistant; and one cook and three assistants.

The hospital has received promises of five or six motor-cars and motor ambulances, to be driven by English chauffeurs. It will take out a complete theatre equipment, instruments, sterilisers, &c.; a complete X ray apparatus, with dynamo, which will also be used for electric lighting; beds and bedding for 60 patients; complete ward equipment; large stores of dressings, anaesthetics, and drugs; and large household stores. Generous support has been given to the hospital, but it still appeals, not only for money to maintain its work, but also for gifts of clothing, bed linen, dressings, and drugs. All donations should be sent to the honorary secretary, Mr. James Baird (cheques crossed Messrs. Cox and Co.), 50A, Curzon-street, W. All gifts in kind should be sent to 10, Stratford-place, W., marked "Urgency Cases Hospital."

We earnestly hope that many members of the medical profession in this country will help, to the best of their power, the good work of this hospital in France.

We are, Sir, yours faithfully,

LAUDER BRUNTON.	E. L. C. EDEN.
W. ARBUTHNOT LANE.	HERBERT POWELL.
A. W. MAYO-ROBSON.	JAMES BAIRD,
STEPHEN PAGET.	Hon. Secretary.

50A, Curzon-street, W., Feb. 22nd, 1915.

PREVENTION OF FROST-BITES.

To the Editor of THE LANCET.

SIR,—In the short article which appeared in THE LANCET on Feb. 6th I have stated briefly the results of some experiments which I had made with oiled silk bags. Several inquiries which I have received since that date have made me realise that the principles which had guided me had not been understood. I propose, therefore, to give shortly a fuller account of my experiments. Meanwhile, I would like to make it clear that the oiled silk was not used by me on account of its low thermo-conductivity or of its superiority to indiarubber as a waterproofing agent. My object was to use the air space between the bag and the skin as the protective agent on account of its low conductivity. The thick woollen sock or pair of socks between the skin and the bag act as a support for the bag, and the knitted wool, which is itself a bad heat conductor, holds the air in its meshes. The thin sock placed outside the bag is intended to protect the bag against injury. It is obvious that to obtain the best results the boots must not be tight or laced tightly. Any waterproof material would act in the same way as oiled silk, the object of which is to prevent the penetration of water in the air space and the soaking of the skin. The oiled silk was selected by me on account of its cheapness, of its softness and adaptability, and of the ease with which damages to it can be repaired.

This method of prevention is based upon well-known physical and pathological principles, which I did not think it necessary to discuss in a preliminary communication.

I am, Sir, yours faithfully,

SHERIDAN DELÉPINE,
Director, Public Health Laboratory.

Manchester, Feb. 23rd, 1915.

CAN EXOPHTHALMIC GOITRE BE SPREAD BY CONTACT?

To the Editor of THE LANCET.

SIR,—Exophthalmic goitre is presumably due to a toxæmia, and there is at the present time an increasing belief that this is the result of some infective condition, probably of intestinal origin. Such a view is strengthened by analogy with McCarrison's work on endemic goitre in India, for there seems little doubt that some intestinal excitant is at the bottom of this condition.¹ There is no doubt about the fact that exophthalmic goitre tends to run in families. This is generally explained as being due to a peculiar susceptibility for the disease in certain families. But is there any evidence that the disease can also be spread by contact from one person to another? My attention has lately been drawn to this latter possibility by two cases of the disease in women, both of whom had intimate friends, not relations, suffering from the same complaint.

The first, Case A, was a patient of the late Sir W. Broadbent, and she discovered she had Graves's disease through comparing her symptoms with those of a friend whom she saw constantly, and who was suffering from it in an advanced stage.

In the second, Case B, more details are available. The patient, a married woman, had a friend who developed Graves's disease in the spring of 1911. She saw this friend once a week pretty regularly for about two years, and in addition the two used to stay in the same house together for a few days

¹ THE LANCET, 1913, vol. i, pp. 147, 219, 365.

three or four times a year. She used to nurse her sometimes. In the spring of 1913 the friend moved away from the neighbourhood, and B's weekly visits stopped altogether. However, they stayed together on several occasions for some days at a time. In the spring of 1914 B herself contracted the disease.

These two cases are to some extent suggestive of the disease being spread by contact. In the case B, however, there was a very considerable interval (viz., three years) between the onset of the disease in the two women, and there is the further point—viz., that B's mother has for some years had symptoms of hypothyroidism, which subside after an occasional course of thyroid extract. Hence to this extent there is a "thyroid history" in the case.

To carry the matter further inquiries were made, through Dr. Hale White's kindness, and answers were received from ten patients who had had exophthalmic goitre. Seven of these had never come across any other cases of the disease so far as they were aware. In the three remaining cases the patients had during their lifetime come in contact with other people suffering from the disease, but in each case the length of time that elapsed between the onset of the disease and the contact was many years, so that they afford no definite evidence in favour of the theory of contacts.

At this stage it seemed the best plan to write and find out if any of your readers have come across cases of exophthalmic goitre among intimate friends, suggesting that the disease could be transmitted by contact. I should be very much obliged for any information on this point.

I am, Sir, yours faithfully,

St. Thomas's-street, S.E., Feb. 20th, 1915. E. P. POULTON.

THE ETIOLOGY OF POLIOMYELITIS.

To the Editor of THE LANCET.

SIR,—I am much indebted to Dr. George Jubb for his letter in THE LANCET of to-day's date, in which, although he is not now in a position to give the exact relative position of stables or cowsheds to the infected houses where cases of poliomyelitis occurred in West Kirby, he is able to state that the same horse and cart took round the milk. As Dr. Jubb admits, this fact in no way diminishes the possibility of stomoxys calcitrans acting as a factor in the infection of the cases which occurred. In my opinion the possibility is materially strengthened, because everyone who has had to do with horses must know how biting flies stick to their victims, annoying them even when on the trot.

That I am quite in agreement with the view that some cases of poliomyelitis acquire infection through human carriers will be adequately illustrated by the following quotations from a Brief Note on Two or Three Interesting Carrier Problems in the Epidemiology of Summer Diarrhoea, Infantile Paralysis (Poliomyelitis), and Pellagra, which appeared in *Public Health*, the journal of the Society of Medical Officers of Health, in December, 1914. In the course of this paper I say:—

The channel of infection (of poliomyelitis) is, of course, of importance, particularly from a preventive point of view. Epidemiological evidence points strongly to the existence of human "carriers," as in a few of the Norfolk cases, and the virus has been found in the naso-pharyngeal secretions of contacts. Fortunately there appears to be a natural human insusceptibility to the disease which limits the spread of poliomyelitis by the channel of the nasal or pharyngeal mucous membrane. The maximum prevalence in summer suggests either dust-borne or fly-borne infection. Neustaedter

and Thro¹ state that they have induced the disease in monkeys by inoculating them with dust from sick rooms. That infection can be conveyed by stomoxys has been definitely proved by Anderson and Frost. There are, then, as it seems to me, three principal methods of conveyance of infection: (1) By direct contact with a sufferer or a human carrier; (2) by an insect carrier (more suspicion attaches to stomoxys than any other insect, and there is now direct evidence of its conveying infection); (3) dust.

I then discuss the methods of prevention on the assumption that these methods of conveyance of infection are rightly designated, but having already unduly encroached on your space those interested will please refer to the original article.

I am, Sir, yours faithfully,

J. T. C. NASH,

County Medical Officer of Health.

The Shirehouse, Norwich, Feb. 20th, 1915.

FAITH AND ASTIGMATISM.

To the Editor of THE LANCET.

SIR,—Dr. S. Johnson Taylor, in THE LANCET of to-day's date, is endeavouring to confuse the issue between us. Because he has not been successful in the prescription of low cylinders he says these are of no benefit or effect. On the other hand, in my experience, certain cases have been considerably relieved by their use, hence my advocacy of them; and as my conception of a true physician is one who does all in his power to alleviate man of the ills from which he suffers, therefore, if the correction of a low degree of astigmatism cures a patient, no other treatment being employed, the inference is obvious. Except as padding, there seems to be no necessity for dragging into the discussion the Old Bailey, Harrogate, the Langham Hotel, politics, nor the Church, but Prey's letters, which I mentioned, are an exceedingly useful test for astigmatism.

On one point I am quite in agreement with Dr. Taylor—that is, in the great advantage of experience in general practice before taking up a specialty, and it was during my 10 years as a general practitioner that these cases, due to uncorrected astigmatism, first came under my notice, and a further 14 years as an oculist have convinced me that many patients derive benefit from the correction of low degrees of astigmatism, and the correction required can only be ascertained by an accurate examination, and finally, the glasses prescribed must be precisely fitted.

As it is evident nothing will persuade Dr. Taylor that there are two sides to every question, this will be my last contribution to the discussion.

I am, Sir, yours faithfully,

Harley-street, W., Feb. 20th, 1915. REGINALD EVERSHED.

TREATMENT OF CEREBRO-SPINAL MENINGITIS.

To the Editor of THE LANCET.

SIR,—I see from reports that there have been cases of cerebro-spinal meningitis (meningococcal) at the Crystal Palace and that eight cases have proved fatal. While house physician and assistant pathologist at the Leicester Royal Infirmary I had the opportunity of treating five such cases under Dr. T. A. Johnston of that institution.

All the cases after lumbar puncture showed the typical diplococci both in culture and staining

characteristics, and I outline the method of treatment. Lumbar puncture was performed on admission with examination of a centrifuged specimen of the cerebro-spinal fluid. Within six hours the cerebro-spinal fluid was allowed to drain out till the drip was of normal rapidity, this giving about 50-70 c.c. of the fluid in all cases. 60 c.c. of blood were then drawn from the arm of a healthy relative and the blood centrifuged. About 20 c.c. of this fresh human serum were then mixed with 30 c.c. of Flexner's meningococcic serum, and this mixture injected into the spinal canal between the third and fourth lumbar spines. Five grains of soamin were injected intravenously each day in two cases. Chloroform was administered in each case and the bottom of the bed raised one foot. This procedure was repeated daily for five days, the temperature during that time showing a sharp rise with each injection, but the pulse remaining 80-90 per minute. The injections were discontinued after five days and the temperature immediately fell to normal, and oscillated between 98°-100° F. during convalescence, getting steadier each day.

In only one case was there a relapse, and another injection of the human serum with meningococcal serum was all that was necessary. Pain was acute in some cases after injection and morphia or omnopon was administered freely. One case had neuralgic pains down the legs, due to injury of the nerves of the lumbar region, but phenacetin and aspirin combined in large doses relieved this.

All the cases recovered and left hospital apparently normal, mentally and physically.

I am, Sir, yours faithfully,

NORMAN P. LAING,
Lieutenant, R.A.M.C.

Blackpool, Feb. 19th, 1915.

MILD SMALL-POX.

To the Editor of THE LANCET.

SIR,—May I supplement Sir William Osler's letter in to-day's issue of THE LANCET by recommending a study of Dr. Robert Willan's "Description and Treatment of Cutaneous Diseases," which was published in 1808, and republished with some additions in 1840 by Dr. T. Bateman; also Dr. Willan's article on small-pox, illuminated by a very beautiful coloured illustration, in the *Edinburgh Medical Journal* for 1807. The article is of value as it draws attention to the fact that though the amount of the rash influences the prognosis it does not assist in the diagnosis, and then proceeds to point out the characteristic features of the rash of small-pox by which it may be distinguished from skin diseases.

I am, Sir, yours faithfully,

Dublin, Feb. 20th, 1915.

GEORGE FOY.

IODISED PHENOL AS A DRESSING.

To the Editor of THE LANCET.

SIR,—In the treatment of burns of second degree and all forms of abrasions I should like to call your attention to the value of iodised phenol. Cut away all blisters and paint the whole surface with iodised phenol, being particular to get it well into the angle between the raised epidermis and the true skin. Then cover with sterilised plain gauze and absorbent wool. It is surprising how little pain is felt either during the dressing or afterwards. I repeat the process daily and find that in a week to 10 days the whole surface of a burn has healed without suppuration or even surrounding redness. Recently I treated a child aged 18 months in

this way who had been burnt with benzine from the middle of the leg to the middle of the thigh and round three-fifths of the circumference of the limb. No lotion of any kind was used, and in spite of the dressings being soaked with urine the burn was completely healed by the tenth day. The mother of this child had both her hands burnt at the same time, and as she was obliged to go on using them I did not remove any unbroken skin at first. In her case the healing was much quicker where the skin was removed at once, but she was quite well in 14 days, and said there was very little pain.

I am, Sir, yours faithfully,

Hastings, N.Z., Jan. 7th, 1915.

ROBERT NAIRN.

THE WOUNDED ALLIES RELIEF COMMITTEE.

To the Editor of THE LANCET.

SIR,—The letter in your issue of Feb. 20th dealing with the appeal of the Wounded Allies Relief Committee, signed by Dr. James Donelan, unfortunately conveys a completely erroneous impression of our activities.

The Wounded Allies Relief Committee is not a new organisation, but was started last August, and has already earned the thanks of the British and Belgian authorities. The committee has taken over certain liabilities with regard to Anglo-French hospitals under pre-existing arrangements made with the French military authorities, but this section of its work is only a small department. The Wounded Allies appeal is for Belgium, Serbia, Montenegro, for motor ambulances, a hospital ship, motor kitchens, and other things. Hospitals for the French wounded are perhaps less than one-tenth of the committee's liabilities. The liabilities taken over by the committee are liabilities under arrangements made with the French military authorities under the ægis of a branch of the French Red Cross in France.

I am, Sir, yours faithfully,

L. HADEN GUEST.

Tavistock-square, W.C., Feb. 24th, 1915.

Obituary.

STANLEY RISELEY, M.D., C.M. EDIN.,

CONSULTING OPHTHALMIC SURGEON TO THE ROYAL HOSPITAL,
SHEFFIELD.

Dr. Stanley Riseley passed peacefully away on Feb. 5th at the early age of 47, after a long and distressing illness, borne with patience and fortitude.

Stanley Riseley was a native of Bristol, the son of Mr. Henry L. Riseley, ex-sheriff of that city. He studied medicine at Edinburgh University, where he graduated as M.B., C.M. in 1891, and took the M.D. in 1893. He held various resident posts, including that of house surgeon at Halifax Infirmary and Rotherham Hospital. After serving as clinical assistant at Moorfields and ophthalmic assistant at Middlesex Hospital, he went to Sheffield in 1898 and was elected ophthalmic surgeon to the Royal Hospital. He resigned last year on account of ill-health, and was elected consulting surgeon. For several years he was secretary of the honorary staff, and represented it on the board of management. For some years also he was ophthalmic surgeon to the Rotherham Hospital and the Chesterfield and North Derbyshire

Hospital, and a medical referee for ophthalmic cases under the Workmen's Compensation Act. In 1912 he was President of the Sheffield Medico-Chirurgical Society. He was a major on the staff of the 3rd Northern General Hospital, but illness prevented his being able to undertake active duty. His contributions to medical literature were few, but displayed sound knowledge and ripe judgment. A correspondent writes: "His thorough and painstaking methods, his great kindness and sympathy, gained for him a large consulting ophthalmic practice. In earlier days he was well known, as also were his two brothers, amongst the leading tennis players in the kingdom, and later he was a moving spirit in the Hallamshire Lawn Tennis Club. His frank and straightforward manner, together with an almost boyish enjoyment of life, made his personality a very attractive one, and his untimely end will be sincerely and widely deplored."

Dr. Riseley married in 1901 the only child of the late Dr. Cleaver, of Sheffield. His widow and five children survive him. The funeral, which took place at Ecclesall Church, Sheffield, on Feb. 9th, was very largely attended.

THOMAS WESLEY MILLS, M.A., M.D. MCGILL,
L.R.C.P. LOND.,

EMERITUS PROFESSOR OF PHYSIOLOGY, MCGILL UNIVERSITY.

THIS well-known Canadian teacher and writer died suddenly on Feb. 13th in London of angina pectoris. Dr. Mills was born and educated in Canada. He took his B.A. at the University of Toronto and his M.B. at McGill University in 1878. He was for several years demonstrator of physiology with Professor Osler, and studied at University College with Sir John Burdon-Sanderson and Professor Schäfer. In 1884 he became lecturer in physiology and in 1886 professor of the subject at McGill. He organised the teaching of physiology on modern lines, and was the first Canadian teacher of the subject to have a thoroughly up-to-date, well-equipped laboratory. Among his early contributions to physiology were the studies on cardiac innervation. He was one of the first to follow the fruitful lead of Gaskell. He became much interested in comparative physiology, and the results of a long series of studies are embodied in a work on the nature and development of animal intelligence. In 1889 appeared his "Text-book of Animal Physiology," which was modified in the new edition in 1890 to a "Text-book of Comparative Physiology." He was passionately devoted to music, and in his younger days was himself no mean performer on the violin. In 1906 appeared his "Voice Production in Singing and Speaking," which brought him much reputation outside of medical circles. After a serious illness, he retired in 1910, and had lived in London, devoting himself with extraordinary energy and enthusiasm to the study of modern music.

UNIVERSITY OF LONDON OFFICERS TRAINING CORPS.—The commanding officer of this corps (Lieutenant-Colonel D. S. Capper) asks us to announce that a limited number of young men who are not students of the University will be enrolled for a course of continuous training with a view to qualifying for commissions. Candidates, who must be between the ages of 18 and 28 years and suitable in every respect for commissions in the army, should attend in person to see the adjutant of the contingent at headquarters, University of London, South Kensington. The next course of continuous training will commence on March 15th.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE week's subscriptions to the Fund are very satisfactory, mainly owing to a large anonymous donation of £300 from Dunedin and to handsome subscriptions from Sheffield and District and from the Ontario Medical Association of £250 and \$1000 respectively. "U.C.A.L." sends £82, and the British Milk Products Company a fourth contribution representing a royalty on the sale of Sanaphos. These royalties have now brought nearly £170 to the Fund.

The donation of £100 from the nurses of the Civil General Hospital at Rangoon, announced last week, consisted of part of the proceeds of a very successful entertainment given by the nurses in aid of funds arising out of the needs of the war. We are informed by the nursing superintendent that the total raised was £120, of which £20 were allotted to the fund for North Sea seamen and aviators, but the nurses desired that the larger part should be given to the Belgian Doctors' and Pharmacists' Relief Fund as an expression of their sympathy with those professions, to which the nursing profession is a sister.

IMPORTANT MEETING IN NEWCASTLE.

A meeting of medical men and pharmacists of the Newcastle and Durham districts was held at the Medical College, Newcastle-on-Tyne, on Wednesday, Feb. 17th, when Professor Rutherford Morison presided at a crowded meeting in the lecture theatre.

Professor Morison stated that all the doctors and pharmacists of the north had been invited to the meeting, the object of which was to discover means of helping the Belgian doctors and pharmacists. These could only be helped pecuniarily now. The object of the Fund they were met to support, the Belgian Doctors' and Pharmacists' Relief Fund, was to help towards their reinstatement, and it would not be long before they would get their country back.

Professor C. Jacobs, Professor of Obstetrics in the University of Brussels, then reviewed the recent experiences of his country. Their homes, villages, and towns were destroyed: they might be sorely wounded, but they were, he said, unconquerable. Notwithstanding its "Kultur," Germany had been misled, and had made a grand mistake in invading Belgium. Whatever might be the outcome of this titanic struggle, Germany would be marked eternally as criminal. Germany had been deceived by the grandeur and glitter of her military staff. In Belgium now there were no Flemish, no Walloons, no Liberals, no Conservatives, and no Socialists. They were all one in the struggle for national liberty, awaiting the day of expiation. Germany, in striking her cowardly blow, had coveted control of Belgian riches and treasures, and had feared Belgian competitors for the German trade and industry. His glorious land was as ruined as Pompeii. But the Belgians would sow new harvests, and through insistent endeavour build up a greater fortune in the future. They could never rest until their country was free and avenged, and they knew these things would come, their national flag would fly again, and their gallant King Albert reign. Their devotion to their King and Queen was complete; every boy was being christened Albert and

every girl Elizabeth. Belgium would never die. Never would Belgians part with the spirit to do till the last their duty as they had ever done it. As the spokesman of his Belgian colleagues, he appealed to the doctors and pharmacists that an impulse of international fraternity might come to the aid of Belgian doctors and pharmacists. Those who had remained in the captured towns had done so out of a sense of duty. They had suffered indescribably. Some had been taken as hostages. Twenty-seven had been shot. Widows and orphans had been left deprived of everything. He called upon the medical profession of the whole world, except Germany, to rally to Belgium's help. He had been under German control for three months. Before the Germans took from him his motor-car he had himself been able to see many atrocities, and what the Belgians said of the atrocities, he assured his audience, was not a hundredth part of what the Germans had done in Belgium. He showed on the screen photographs of the havoc wrought in Louvain, Dinant, Malines, and Charleroi.

Sir Thomas Oliver moved a resolution of sympathy with Belgium, to which country the Allies owed an incalculable debt, and of thanks to Professor Jacobs.

Dr. Turner seconded in eloquent terms, and the resolution was carried by acclamation.

Dr. Durant moved and Dr. James Smith seconded a resolution, which was carried, forming a representative committee to raise funds.

Of this committee Professor Rutherford Morison was chosen as chairman, Dr. James Don (1, Grove-street, Newcastle) and Mr. A. S. Percival, M.B. (17, Claremont-place, Newcastle), being the honorary secretaries. The committee is representative of North Northumberland generally, of Newcastle, Gateshead, Sunderland, Cleveland, Tyneside, Morpeth, Bishop Auckland, Blyth, Darlington, Consett, Durham, Hartlepool, Hexham, South Shields, and Stockton. In addition to the officers mentioned, the senior physicians and surgeons of the general hospitals in many of the cities have joined the committee, and among other names are those of Sir G. H. Philipson, Professor R. Howden, Dr. W. D. Arnison, Sir Thomas Oliver, Professor H. Hutchens, Mr. G. Grey Turner, Dr. J. W. Smith, and Professor Ranken Lytle.

THE MOVEMENT IN MANCHESTER AND DISTRICT.

An important meeting was held in the medical school at Manchester on Thursday, Feb. 18th, when Professor Jacobs delivered a stirring address to an interested meeting. Professor Archibald Donald presided.

Professor Jacobs said that Germany had erred terribly in invading Belgium, and would be branded for ever with the mark of the criminal. Belgium was once more the battlefield of Europe; the Belgians had to mourn the loss of countless dead, but they kept in their hearts an undying faith in the triumph of the Belgian cause. He pointed out that Belgian doctors and pharmacists had not been spared in the general suffering, and he appealed to the medical and pharmaceutical world that an impulse of international fraternity might come to their aid. Was it realised, he asked, what Belgium had suffered and was suffering? Duty had bound doctors and pharmacists to their posts in entirely ruined localities; some were carrying on their profession as best they could in the ruined remains of houses, and others had improvised other make-shift shelter. Some had had to work as

navvies in order to have a few pence in their pockets; others had not seen bread for a fortnight, but had lived exclusively on potatoes. Others had a meagre bunch of straw laid on the bare ground for their bedding. He had seen doctors dressed in torn garments and their children in rags. One of his colleagues had to live on wayside herbs for three days and three nights, and his wife shared his fate. Some of their ranks had been taken as hostages, others had been shot, and their widows and orphans left deprived of everything. Belgium, he said, contained 4800 doctors, and at least 1000 of them were now absolutely poverty-stricken and from 2000 to 3500 were suffering cruelly through the war. They had 1800 pharmacists, and at least 300 of them were unable to earn their living, and all, with very few exceptions, were deprived of the most necessary trading stock. These practitioners had given a lesson to the world of unflinching energy, but now their breaking courage would have to be kept up. In this emergency he called on the medical and pharmaceutical professions to rally to their help.

The following subscriptions were received at the meeting:—

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Ltd. £6900 had passed into the Treasurer's hands by Tuesday last, the sum not including the Scottish and Irish and several large local funds.

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries acknowledges with thanks the receipt of surgical instruments from the following donors:—

Dr. A. Hill Joseph, Bexhill-on-Sea; Dr. W. T. Handley, New Cavendish-street, W.; Dr. Mary C. Bell, Harley-street, W.; Dr. G. H. Colt, Aberdeen; Dr. Leishman, Slough; and Dr. Purslow, Birmingham.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—J. E. Cheesman (Sections I. and II.), St. Mary's Hospital; A. E. Gravelle (Sections I. and II.), King's College Hospital; I. F. Mackenzie (Sections I. and II.), Guy's Hospital; A. G. Williams (Sections I. and II.), Cambridge and St. Bartholomew's Hospital; and A. H. Willson (Sections I. and II.), London Hospital.

Medicine.—M. M. Burt (Sections I. and II.), Birmingham; J. R. Crolius (Sections I. and II.), Edinburgh and London; C. S. Dodson (Sections I. and II.), Cambridge; A. Glen (Sections I. and II.), Sheffield; I. F. Mackenzie (Sections I. and II.), Guy's Hospital; E. M. Townsend (Sections I. and II.), Middlesex Hospital; and A. G. Williams (Sections I. and II.), St. Bartholomew's Hospital.

Forensic Medicine.—M. M. Burt, Birmingham; F. W. Chamberlain, Middlesex Hospital; J. R. Crolius, Edinburgh and London; H. A. De Morgan, Middlesex Hospital; L. A. J. Graham and I. F. Mackenzie, Guy's Hospital; D. C. Ogilvie, Middlesex Hospital; A. L. Robinson, University College Hospital; A. G. Williams, St. Bartholomew's Hospital; and A. H. Willson, London Hospital.

Midwifery.—R. H. Chadwick, Leeds; J. R. Crolius, Edinburgh and London; J. D. Ferguson, Leeds; L. A. J. Graham, Guy's Hospital; L. Kahan, London Hospital; I. F. Mackenzie, Guy's Hospital; W. H. Rhys Jones, Charing Cross Hospital; A. G. Williams, St. Bartholomew's Hospital; and G. C. Wright, London Hospital.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: M. M. Burt, A. E. Gravelle, I. F. Mackenzie, E. M. Townsend, and A. H. Willson.

UNIVERSITY OF OXFORD.—Dr. Alexander Hill Griffith has been nominated to act as an examiner for the 1915 and 1916 examinations for the Diploma in Ophthalmology.

MENTAL AFTER-CARE ASSOCIATION.—The annual meeting of the Mental After-Care Association for Poor Persons Convalescent or Recovered from Institutions for the Insane will be held at Bethlem Royal Hospital, St. George's-road, S.E. (by permission of the governors of the hospital), on Tuesday, March 2nd, at 3 P.M. The chair will be taken by Dr. Henry Rayner, chairman of the association.

ASSOCIATION FOR PROMOTING THE TRAINING AND SUPPLY OF MIDWIVES.—The eleventh annual meeting will be held, by permission of Miss Lorent Grant, at 75, Barkston-gardens, London, S.W., on Thursday, March 11th, at 3 P.M., when the chair will be taken by Mrs. Humphry Ward. A short address on the Present Position of the Midwife will be delivered by Miss S. M. Glass.

THE Royal Dental Hospital, Leicester-square, has received a donation of £100 from the Worshipful Company of Grocers. The annual general meeting of the governors will be held on Thursday, March 11th, at 5.30 P.M., the Hon. Harry Lawson presiding.

UNDER the will of the late Miss Marjory S. Shaw, of Glasgow, a sum of £500,000 will be divided among charitable institutions at the discretion of the trustees.

The War.

THE HONOURS LIST.

FOLLOWING Sir John French's despatch dated Jan. 14th, and the list of names brought forward by the Commander-in-Chief for gallant and distinguished service in the field, the King has approved of a long list of rewards "for services rendered in connexion with Operations in the Field." The following are the medical officers promoted or appointed to orders:—

Staff.

Colonels (temporary Surgeon-Generals) R. Porter and J. J. O'Donnell, D.S.O., promoted Surgeon-Generals. Major (temporary Lieutenant-Colonel) H. Ensor, D.S.O., promoted Brevet Lieutenant-Colonel.

Surgeon-General Sir Arthur T. Sloggett, C.B., C.M.G., K.H.S., promoted K.C.B.; Surgeon-General T. P. Woodhouse, Colonel M. W. O'Keefe, Colonel E. H. L. Lynden-Bell, and Colonel S. Hickson, K.H.S., appointed C.B.'s.

Colonel R. H. S. Sawyer and Colonel F. H. Treherne appointed C.M.G.'s.

Captain E. L. Moss awarded the Military Cross.

Royal Army Medical Corps and Medical Services.

Bt. Cols.—Lieut.-Cols. A. J. Luther and C. B. Lawson.

Bt. Lieut.-Cols.—Majs. A. W. Hooper, D.S.O., E. W. Bliss, and M. H. G. Fell.

K.C.M.G.—Lieut.-Cols. (tempy. Cols.) G. H. Makins, C.B., and Sir A. A. Bowlby, C.M.G.

C.B.—Surg.-Gen. W. G. Macpherson, C.M.G., K.H.P., Col. F. W. C. Jones, Bt. Col. Sir W. B. Leishman, K.H.P., F.R.S., and Col. (tempy.) Sir J. Rose Bradford, K.C.M.G., F.R.S.

C.M.G.—Lieut.-Cols. G. H. Barefoot (tempy. Col.), C. H. Burtchall, L. T. M. Nash, B. Forde, and G. S. McLoughlin, D.S.O.; Majs. G. T. K. Maurice and E. T. F. Birrell.

D.S.O.—Majs. H. R. Bateman, C. R. Evans, C. M. Goodbody, L. W. Harrison, H. L. W. Norrington, F. A. Stephens, F. A. Symons, V. J. Crawford, A. C. Fox, G. J. A. Ormsby, and N. J. C. Rutherford; Cpts. A. G. Wilson, S. J. A. H. Walshe, and E. T. Potts.

Military Cross.—Cpts. C. Kelly, E. C. Phelan, W. B. Purdon, W. F. M. Loughnan, T. H. Scott, Tempy. Lieut. J. R. Waddy, Lieuts. W. Tyrrell, W. McK. H. McCullagh, Tempy. Lieut. W. W. Ingram, Lieuts. J. FitzG. Gwynne, F. C. Davidson, Tempy. Lieut. E. W. Carrington, Lieut. T. H. Balfour, Sgt.-Majs. W. H. Storey, R. J. Fleming, A. Baker, A. Bennett, J. J. Earp, and H. J. Reeve.

Hon. Capt.—Qmr. and Hon. Lieut. E. J. Buckley.

Indian Army.

Bt. Col.—Lieut.-Col. A. H. Moorhead, I.M.S.

Bt. Lieut.-Col.—Maj. J. M. Sloan, D.S.O.

Military Cross.—3rd Class Asst. Surg. F. B. A. Braganza.

LIEUTENANT ARTHUR MARTIN LEAKE, V.C. (CLASP).

In the *London Gazette* of last week, among the awards of the Victoria Cross to officers and men for conspicuous acts of bravery and devotion to duty whilst serving with the Expeditionary Force, appeared this announcement:—

Lieutenant Arthur Martin Leake, R.A.M.C., who was awarded the Victoria Cross on May 13th, 1902, is granted a clasp for conspicuous bravery in the present campaign.

The following is the description of the act of gallantry which earned Surgeon-Captain Martin Leake, as he then was, the Victoria Cross in the South African War: "While tending the wounded under heavy fire from 40 Boers at 110 yards range at Vlakfontein he was shot three times, but although grievously hurt he refused water to relieve his own thirst until all the others (eight) had had some." The extremely rare distinction of a clasp to the

Victoria Cross has now been awarded to him on the following ground:—

For most conspicuous bravery and devotion to duty throughout the campaign, especially during the period Oct. 29th to Nov. 8th, 1914, near Zonnebeke, in rescuing whilst exposed to constant fire a large number of the wounded who were lying close to the enemy's trenches.

Lieutenant Martin Leake was educated at University College Hospital, and at the time of the South African War went to South Africa in 1900 with the Hertfordshire Yeomanry. On the return of that regiment he remained to join Baden Powell's Police. In September last he rejoined the army with the temporary rank of Lieutenant in the Royal Army Medical Corps. The whole medical profession unites in honouring him.

THE CASUALTY LIST.

The casualties among officers in the Expeditionary Force reported since our last issue include the name of Lieutenant Donald Campbell, R.A.M.C., who obtained a temporary commission in December last. Captain J. A. T. Bell, of the New Zealand Medical Corps, is also reported killed. In the recent serious rioting at Singapore Lieutenant A. F. Legge, Singapore Volunteer Medical Company, Dr. P. N. Gerrard, of the Federated Malay States Medical Service, and Dr. E. D. Whittle were killed. Lieutenant L. Courtauld, R.A.M.C., is reported wounded.

On board H.M.S. *Clan McNaughton*, which has been reported a total loss, were Staff-Surgeon W. Graham Moore-Anderson, R.N., and Surgeon-Probationer R. O'C. Redmond, R.N.V.R.

THE BRITISH SCIENCE GUILD ON ANTITYPHOID INOCULATION.

The British Science Guild, whose executive committee contains names illustrious in nearly every branch of science, has recently published a resolution of its medical committee condemning the publication by lay journals of advertisements by the British Union for Abolition of Vivisection attempting to dissuade soldiers undergoing antityphoid inoculation. One notoriously discreditable advertisement, subsequently disowned by the journal that published it, is referred to, and particularly the following sentence is condemned as untrue: "Inoculation (proved to be an utterly useless and dangerous practice) is forced upon intelligent objectors, even as the Germans would force their 'Kultur' upon unwilling Europe." The committee has not seen a single scientific treatise of any value which has succeeded in proving the inoculation to be "an utterly useless and dangerous practice, and does not believe that such a scientific treatise has ever been even attempted." The committee then quotes the names of the officers of the union: Dr. Walter Hadwen, Viscount Harborton, Lord Tenterden, Mr. H. G. Chancellor, M.P., and Miss Beatrice E. Kidd, and states that it does not think that these persons have ever made such researches into typhoid inoculation, or indeed into pathological and sanitary problems in general, as to justify them in posing as arbiters on a question of this nature, which requires the most expert and impartial consideration. Then protesting against the publication by lay papers of any such one-sided statements by unscientific societies, the committee exposes the situation tersely:—

No scientific theorem is accepted nowadays by scientific men without the consideration of a vast amount of evidence,

generally contained in innumerable scientific publications, the presentment of which even in abstract would fill whole numbers of any daily or weekly periodical. On the other hand, any ignorant or unreasonable person can express in a single sentence his disbelief of this evidence, and thus attempt to dissuade the public from availing themselves of the advantages which science has conferred. Those who are seeking to benefit humanity by medical research are therefore always placed at a disadvantage in public discussions of this kind, because they cannot give a full statement of their arguments, except in a lengthy scientific form, whereas antiscientists can always pretend in a few words that such evidence has been refuted.

The committee appeals to the editors of British periodicals to set their face against the publication in the future of such advertisements, and endorses the satisfaction expressed by the military and medical authorities with the results of the antityphoid inoculation of our troops in the present campaign. The protest is convincingly expressed, and renders a service to truth not only as regards medicine and science, but as regards every technical subject of discussion in which the judicial weight of evidence is countered by an easy and irresponsible denial.

THE EPSOM AND EWELL WAR HOSPITAL.

Much discussion has been taking place in the daily press and questions have been asked in Parliament in regard to the call made upon the committee of the Epsom and Ewell War Hospital to vacate the premises for the racing season, which, although spread over three months, actually occupies only six days—viz., two days in April for the Great Metropolitan and the City and Suburban, and four days in June for the Derby and the Oaks.

The facts appear to be as follows. Soon after the beginning of the war the Grand Stand Association of Epsom Racecourse generously offered the use of the new annexe to their Grand Stand, which was completed and furnished only a few months before the war for a restaurant during race meetings, and which has never been used, to a committee of doctors and residents of Epsom for use as a hospital for sick and wounded soldiers from the front and for such troops as might be quartered in the neighbourhood. The stipulation was, however, made that at the end of six months—viz., on March 6th—the annexe should be restored to its owners to be prepared for use during the racing season as a restaurant and to provide sleeping accommodation for the large retinue of waiters and others employed during the meeting. The hospital committee accepted the use of the building on these terms and proceeded to equip it adequately at a cost of several thousand pounds and convert it into a well-staffed military hospital of 100 beds, in which capacity it has done admittedly excellent work ever since, caring for a large number of our own wounded from the front, including a few Belgian soldiers, and for the troops billeted or encamped in the neighbourhood. The discussion arose over the fact that the Grand Stand Association called on the hospital committee in accordance with the stipulation to hand over the building from the date agreed on, March 6th, that it might be put in order for its original purpose. This course would naturally entail expense, and to some extent danger, through the removal of the 75 patients in hospital; also there would be difficulty in finding other adequate accommodation in the neighbourhood, and this at a time when the

war hospital accommodation generally needs increasing to a considerable extent. Even locally negotiations are going on to take over one of the asylums so as to provide an additional 2000 or 3000 beds. On behalf of the Association it was claimed that a bargain is a bargain; that the hospital has had the valuable use of the building, together with beds, blankets, and kitchen equipment free for six months, and that it could have them again when the racing season ends early in June; and that the Association has already incurred the cost necessarily attendant on wear and tear, so that it was considered somewhat unreasonable that it should be asked in addition not only to forego the possibility offered by its short season to recoup itself to some extent for all the expenses of the idle season, of which the hospital has had all the benefit, but to add to its expenses by providing sleeping accommodation for its staff. The contention of the secretary, Mr. Henry Dorling, is that if the hospital occupation should continue without a break the Government might commandeer the building and pay compensation for the loss of its use. On the other side the hospital committee have recognised, like Mr. Dorling, that a bargain is a bargain, and made the following points: The Association has got along from the beginning until this year without the restaurant building, and in view of the altogether unprecedented and serious state of national affairs it might continue to do so this year. The hospital was equipped and is supported by the liberal contributions of Epsom people, and the work of the medical staff and much of the lay work are voluntary, while if the hospital has to be removed for three months the expense of removal and return will fall on the subscribers, while such removal would hardly be free from at least serious inconvenience to some of the patients. Save for a small cottage hospital in Epsom, only just sufficient for local needs, there is no other provision for several miles round for civil needs and none at all for military cases, while hospital accommodation is constantly needed for the 5000 recruits stationed in and around Epsom. Moreover, the exceptional suitability in all respects of the building to its present purpose, its convenience in the matter of locality, and its unexampled salubrity all render it impossible of replacement. On all these counts the feeling in Epsom itself, including even the greater part of the sporting element, which is quite powerful there, is strong that the exceptional situation imperatively demanded whatever sacrifice on behalf of King and country might be requisite at this crisis. This feeling was well expressed by the Duke of Portland, who in a letter to the *Times* of Feb. 19th said that when this country was coping with a Herculean task more formidable than any with which she had tried conclusions in the course of her history, it was nothing less than the duty of all men, racing men included, to subordinate their own to the common interest. It is with real satisfaction that we now learn that arrangements satisfactory to all parties have been made as a result of a conference between the Grand Stand Association, the hospital authorities, and the War Office. The hospital authorities are to continue in occupation of the building, but during race weeks one storey, that which is connected with the grand stand by a bridge, will be placed at the disposal of the Grand Stand Association, special arrangements being made during the race meetings for the feeding of the patients.

HÔPITAL ANGLO-FRANÇAIS.—Mr. H. W. Carson sends us the following account of the work of this institution:—The Hôpital Anglo-Français at Le Tréport, Seine Inférieure, which has accommodation for 65 patients, was founded by the Hon. Lady Murray, under the British and French Red Cross, for the reception of wounded French soldiers. It occupies a newly built hotel, which has not as yet been open to visitors, standing in its own grounds of some three acres on the high cliffs south-west of Le Tréport, overlooking the sea. The sanitary arrangements are excellent, practically every room having hot and cold water fitted, and there are many bathrooms. The medical and nursing staff is English, and includes a surgeon, two dressers, three sisters, and three probationers. In addition there is a staff of seven *infirmiers*, French male nurses attached to the army, who do not, however, take any part in the actual nursing. By kind permission of Colonel Clark, R.A.M.C., who is in charge of a 500-bed army hospital on the same estate, the X ray and pathological work is undertaken by members of the Royal Army Medical Corps staff, and this assistance has proved invaluable.

The hospital received its first cases on Dec. 12th when 50 arrived, and since then the average number of beds occupied has varied between 45 and 55. Patients come direct from the front *via* —, and in some cases have arrived within 24 hours of their receipt of injury. But the time varies very much and averages perhaps nearer three days. The last part of the journey —, about 28 miles, is done by motor ambulance, a rather trying journey, as at this time of year the roads in Northern France are not at their best. It may interest readers of THE LANCET to hear some details of cases under treatment. At first a number of perforating wounds of the hand were received, and this is perhaps the commonest form of wound. A rifle bullet wound is a rarity, the great majority being due to shell or bomb, nearly all presenting multiple injuries. Shrapnel wounds are not common. Wounds by bomb explosion, apparently large bombs thrown by howitzers, are sometimes very severe, affecting the limbs chiefly; but, of course, it is probable that abdominal and thoracic wounds from this cause are too severe to be sent to us as we are 50 miles from the front. Wounds of bone are in nearly all cases very severe, the bone being splintered into many fragments at the point of impact. If the femur is fractured it is our experience that a large extravasation of blood occurs, and as this soon becomes septic an abscess forms, often extending widely in the thigh. So far we have seen only two cases where a hole has been drilled through a bone without causing solution of continuity, both rifle bullet wounds, one of the tibia and the other of the ulna. Injuries to nerves have been rare, a division of the ulna nerve in the forearm by a rifle bullet, and the involvement of the musculo-spiral nerve in a severe fracture of the humerus being the only cases noted of late. The following cases have presented some unusual features of interest:—

Shell wound of thigh.—The upper and inner aspect of the right thigh was lacerated by shell fire, causing a wound 10 inches by 12 inches. There was no injury to the femur or to the femoral artery, and the wound is healing satisfactorily.

Bullet wound of temple with destruction of both eyes.—The bullet entered 1 inch behind the outer canthus of the right eye, passed through the right orbit, upper part of the nose, and left orbit, destroying the globes of both eyes. There were no complications, and the patient is doing well.

Fracture of left femur with injury to knee-joint.—Shell wound, fracturing the femur 6 inches above knee-joint and opening the knee-joint by destroying the patella, only a few fragments of which were found. Amputation was necessary above the seat of fracture of the femur.

Abdominal wound.—Patient reached hospital six days after receipt of the injury. Shell wound. A hole 3 inches in diameter just above the symphysis pubis led downwards and to the right, laying bare the right side of the interior of the bony pelvis, fracturing the right os pubis and ischium. The portion of shell had been removed through the right buttock before admission. No injury to bladder or intestines. The wound was very septic, and on the tenth day from the receipt of injury secondary hæmorrhage occurred resulting in death. At no time was there any indication of peritonitis or injury to a hollow viscus. In addition there was a compound comminuted fracture of the right tibia.

Fracture of fibula.—Bullet wound. In this case an aneurysmal varix of the peroneal vessels occurred with effusion of blood into the tissues of the calf of the leg. Mr. W. E. Hills, who was "médecin chef" at the time, was obliged to tie the popliteal artery, and the operation was entirely successful.

These are but a few chosen from a number of severe injuries which this hospital has treated during the two months of its existence. The most noticeable feature is that every case without exception is septic on arrival. Aseptic surgery is not even thought of, and even the most rigid antiseptic treatment appears at first unavailing. Peroxide of hydrogen seems to give the best results, and this and izar are our sheet-anchors and fomentations are the invariable dressing. We have so far had no tetanus cases. Most have had a prophylactic injection of antitetanic serum before arrival, and where this has not been done an injection is given here if the injury is not more than 48 hours old. Perforating wounds of the hand heal very quickly as a rule in spite of the fact that most of them have comminuted fractures of one or more metacarpal bones. The method of healing is practically the same in all—namely, rapid healing of the palmar wound and a more gradual closing of the dorsal, which is delayed by the escape of small pieces of bone. In dealing with fractures of the long bones an effort is made to save all the fragments, but the septic condition prevents plating or wiring operations. A great difficulty is experienced in finding a splint which will keep the fractured ends at rest during the dressings, but in spite of this fractures unite without any marked deformity. We receive patients from all parts of France and French North Africa, and the varieties of patois for those of us who are not linguists make a ready excuse for any difficulty in understanding. We have now under our care, —, who speaks excellent English, but one might well say, in the wards at any rate, "no English spoken here," for the French Tommy is essentially a unilinguist. One carries away a very pleasant impression of the French soldier. He is brave, modest, an excellent patient, and when convalescent full of fun. Their kindness to one another is delightful to witness and their gratitude to their hosts most touching.

THE AMBULANCE DEPARTMENT OF THE ORDER OF ST. JOHN IN INDIA.—The ambulance department of the Order of St. John started work in India as far back as 1888, but it was not until 1900 that any definite attempt was made to establish the Order in that country. Between 1905 and 1908 the work of the association languished, but in 1909 Lord and Lady Minto took up the matter with great enthusiasm, and since that year the progress has been remarkable. In 1908 the total funds in hand were only £20 sterling and now the Indian branch has an ordinary fund of half a lakh of rupees (£4000) and a special Red Cross Fund with a present cash balance of over £10,000 sterling. In 1908 there were only two centres of the association, now there are 300 working actively. On August 7th last, 48 hours after the news of the outbreak of the war reached India, the Indian Council issued a circular letter to its 300 centres, which had been established in all parts of the Indian Empire, asking them to form ladies' committees for the purpose of collecting funds and gifts in kind and material for ambulance detachments should these be formed. A few days later a dépôt for the reception and distribution of these gifts was established at Bombay in extensive premises in one of the best parts of the city.

A special feature of the work of the branch has been to avoid an accumulation of articles of one kind which has occurred in Red Cross work in previous wars, and with this view the medical branch of the army headquarters in India worked out what is called a Unit of Red Cross Gifts, which included the number of articles of various kinds likely to be required for each ten hospital beds. The whole of the collection of gifts in India has been worked on this principle. The number of units despatched to the front has been over 2000, representing a cash value of £40,000. In addition to the despatch of gifts the association has provided a large number of wheeled litters and four motor ambulances for the conveyance of the wounded from the ambulance trains to the special war hospitals for Indian troops which have been established in 12 of the large military cantonments. The Indian Council has remitted £1000 to the Indian Soldiers' Fund and has endowed five beds in the special war hospital which is being organised by the Order of St. John.

in London. It has forwarded considerable sums to the French, Russian, Belgian, and Japanese Red Cross societies and has also given cash grants to the senior nursing sisters of Queen Alexandra's Indian Military Nursing Service proceeding with hospitals from India, and has supplied special consignments for some of these ladies. Its centres have also furnished at short notice trained nurses required for special hospitals. The St. John Ambulance Brigade, which is now firmly established in India, has also been very active, and the whole of the work of removing wounded arriving in hospital ships at Bombay has been entrusted to the Bombay corps of the brigade.

"FROZEN FEET" IN THE FRENCH ARMY.—Our Paris correspondent writes: "Dr. Temoin on Feb. 2nd read before the Académie de Médecine a communication based on a large number of observations by himself and other surgeons in which he points out that there is a class of these cases of so-called 'frozen' feet in which cold is far the least important factor. These 'frost-bites,' attacking often many toes, and resulting in their complete dropping off by gangrene, have been observed in conditions where the temperature has never fallen to freezing point. These false 'frost-bites' have all the appearance of true ones—anaesthesia, redness, the production of phlyctenulae and gangrene. Their pathological mechanism also is the same; they are troubles of local nutrition. Only here these troubles are produced, not by the action of cold, but through the constriction of the feet by the footgear, aided by the slowing of the circulation in the leg, the consequence of the bandages that the French soldiers often use as puttees. The damp aggravates the condition, inducing maceration of the tissues and causing shrinking of the bandages. These eschars and gangrenes are the result of the combined action of inadequately watertight boots too tightly laced and the wearing of too tight bandages. The Russian and German troops, using waterproof and sufficiently loose footgear, and fighting under the same conditions as the French soldiers, have controlled these serious epidemics of 'frozen feet.' Prevention consists in the suppression of leg bandages, the loosening of laces, and the use of fatty substances encasing the entire surface of the foot and leg—oiled paper or greased socks—during the stay of the soldier in the wet trenches. If the frosts come again there will be no more of these so-called frost-bites. Dr. Temoin cites the case of a *chef de service* who, by simply calling on his men when in the trenches to remove their boots for a quarter of an hour twice a day, brought about a considerable fall in the number of 'frozen feet.' Dr. Temoin's paper was considered by the Academy of such importance that it was decided to make an urgent communication of it to the Minister for War."

IRON CROSSES FOR GERMAN MEDICAL OFFICERS.—A Swiss correspondent writes: "German doctors have not been neglected in the lavish distribution of iron crosses. One of the latest lists of recipients contains the names of 138 medical men, of whom 21 are from Hamburg and 8 from Berlin. Three doctors to whom iron crosses were awarded have died at the front. The casualties among Austrian doctors are much higher than those among their German colleagues. A recent list gives the following figures: taken prisoners, 43; missing, 12; wounded, 74; killed, 13; and sick, 121. The attempt to procure Swiss doctors for service on the Austrian-Hungarian battlefields has not been entirely successful. Comparatively few Swiss medical men accepted the invitation in the first instance, and those who crossed into the Dual Monarchy do not seem to have had a particularly happy time. Quite recently three Swiss doctors resigned their positions in the Austrian medical service and returned home. 'Restrictions in responsibility' is the somewhat enigmatic explanation for their action which they have given the Swiss press."

HOSPITAL SHIP TO DUBLIN.—Our Dublin correspondent writes: "A hospital ship, the *Carisbrook Castle*, arrived at Dublin last week carrying some 500 invalided soldiers. In the work of disembarkation the Royal Army Medical Corps was assisted by voluntary aid units of the St. John Ambulance Brigade, under the command of Dr. Lumsden. 100 of the soldiers were sent to Belfast, and the remainder were distributed among the several Dublin hospitals, including the Red Cross hospital in Dublin Castle. Comparatively few of the soldiers are suffering from wounds, but there are many serious cases of frost-bite."

DUBLIN CASTLE RED CROSS HOSPITAL: A ROYAL COLLEGE OF SURGEONS WARD.—A large number of students, past and present, of the Schools of Surgery of the Royal College of Surgeons in Ireland are serving with His Majesty's Navy and Expeditionary Forces. Those at present in the schools anxious to help in any possible way have formed a committee to collect funds to equip a ward in the Dublin Castle Red Cross Hospital, to be called "The Royal College of Surgeons Ward." The honorary treasurers of the committee—Mr. W. H. Carden, Mr. K. Elmes, Mr. J. F. Lyons, Mr. A. Miller, and Miss M. McMullen—will receive and acknowledge subscriptions from old students and their friends.

WOUNDED SOLDIERS IN BELFAST.—Our Belfast correspondent writes: "On Thursday afternoon, Feb. 18th, 110 wounded and invalided soldiers arrived in Belfast from North Wall, Dublin, to which they had been conveyed from Havre in the hospital ship *Carisbrook Castle*. They were transferred from the ship to the ambulance train of the Great Northern Railway Co. of Ireland, which brought them to Belfast, from which they were distributed as follows: to the Military Hospital, Victoria Barracks, Belfast, 20; to the Ulster Volunteer Hospital and the Samaritan Hospital, 35; to the Mater Infirmorum Hospital, 25; to Newtownards Union Infirmary, 20; and to the County Infirmary, Downpatrick, 10. None were sent to the Royal Victoria Hospital. The men are much less seriously injured than the first batch who came home in November and are suffering mainly from frost-bite, rheumatism, and nervous breakdown."

Lieutenant-Colonel Alex. Barclay Lyon, commanding 1st London Casualty Clearing Station, Duke of York's Headquarters, Chelsea, S.W., asks us to state that five medical officers are required in this unit to bring it up to war establishment. Their services would be for the period of the war only.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 17TH.

Paratyphoid Fever amongst the Troops.

Mr. BENTHAM asked the Under Secretary for War whether he would state the number of cases and of deaths from paratyphoid fever amongst British soldiers on the Continent of Europe and in the United Kingdom since August 1st, 1914, and the number of such men who had been inoculated against typhoid fever.—Mr. TENNANT wrote in reply: "In the Expeditionary Force up to Feb. 11th there had been 45 cases of paratyphoid and one death. No information is available as to the number of cases in the United Kingdom nor as to the number of the cases in the Expeditionary Force in which there had been inoculation."

Antityphoid Inoculation in the Army.

Mr. CHANCELLOR asked the Under Secretary for War whether he was aware that typhoid fever was not considered by the medical profession as contagious in the ordinary acceptation of that term, and that until lately typhoid patients had been treated in general hospitals side by side with others and without infecting them; and, if so, whether he would publish a statement to that effect and circulate it throughout the army.—Mr. TENNANT answered: "I am afraid that I cannot agree with my honourable friend. Typhoid is undoubtedly considered to be conveyed by contact, though not to the same extent as scarlet fever, for example, and for some considerable time now special wards in military hospitals have been set apart for these cases."

Mr. CHANCELLOR also asked the right honourable gentleman whether he was prepared from time to time to supply lists of the names and addresses and the condition as regards inoculation of men in the British army who had died from enteric fever.—Mr. TENNANT replied: "The names and particulars as regards inoculation of men in the British army who have died from enteric are invariably obtained and filed at the War Office, and I will consider the possibility of furnishing returns from time to time."

Sickness amongst Troops at the Front.

Lord CHARLES BERESFORD asked the Under Secretary for War whether rheumatism, ague, and weak heart from the effects of rheumatic fever brought about by service at the front were included as casualties.—Mr. TENNANT said in reply: "The figures recently given to the House by the Prime Minister were confined to battle casualties and did not

include cases of sickness. The latter are, however, reported and notified to the relatives in precisely the same manner as other casualties.

Pneumonia in Military Training Camps.

Replying to Sir ALEXANDER HENDERSON, Mr. TENNANT wrote: The number of cases of pneumonia occurring in military training camps in England and Wales during August, September, and October amounts to 494, the number of deaths 68, and the number discharged from the service 10.

The Medical Arrangements at Post Office Centres.

Mr. W. THORNE asked the Postmaster-General whether attendance by the medical officer of his department was compulsory on all sick telephone operators employed at the General Post Office South who were not sufficiently indisposed to remain at home or became indisposed after their arrival on duty; whether complaints had been made by telephonists employed at these exchanges as to delays and the arrangements for patients who desired attention from the medical officers; whether the number of patients who desired attention was daily so large that it was impossible for the doctor to attend to them in the limited time at her disposal, and that operators were frequently asked, after waiting some hours, to postpone their consultation; would he consider whether the number of the staff employed and the number of applications for medical attention would justify the daily attendance of the medical officers from 10 A.M.; and whether he would cause some inquiry to be made into the sufficiency or otherwise of the medical arrangements at the General Post Office South.—Mr. HOBHOUSE replied: The answer to the first part of the question is that if any medical attention is required by a telephonist who is indisposed either on arrival or subsequently, such attention has to be given by a medical officer of the department. No official complaint that I can trace has been made either as to delay or other arrangements. There has been a considerable amount of minor sickness lately and a consequent congestion of patients and some regrettable delay, though no one has been asked to postpone their consultations. It does not appear to be necessary to keep a medical officer in continual daily attendance as there is always a trained nurse at the General Post Office South, and few of the cases are serious. I am calling for a report on the whole question of medical arrangements at those centres where there is a large attendance of staff.

THURSDAY, FEB. 18TH.

The Surgical Treatment of Wounds.

Mr. KING asked the Under Secretary for War whether the army medical authorities had taken steps to derive advantage from the experiments directed to obtain the best antiseptic for wounds as demonstrated by Sir Watson Cheyne at his recent Hunterian lecture.—Mr. TENNANT said in reply: Full advantage has been taken by the army medical authorities of all recent scientific advances in the surgical treatment of wounds.

Temporary Surgeons in the Royal Navy.

Lord CHARLES BERESFORD asked the Financial Secretary to the Admiralty whether young medical officers were entered into the navy as temporary surgeons over the heads of surgeons of the Royal Naval Volunteer Reserve, and on appointment rank as senior to those officers; whether he was aware that very many of these temporary surgeons had lately been students under the surgeons of the Royal Naval Volunteer Reserve, many of the latter officers being consulting surgeons with responsible hospital appointments in civil life; and whether the Admiralty would take steps to have this disability removed.—Mr. MACNAMARA answered: The facts are as stated in the question of the noble lord, and the question is now receiving the consideration of the Board.

First-aid Classes in Ireland.

Mr. BOLAND asked the Chief Secretary to the Lord Lieutenant of Ireland how many first-aid and ambulance work classes had been organised officially through Government departments in Ireland since the outbreak of war; the number of students enrolled; and what further facilities would now be given with a view to the extension of the number of classes.—Mr. T. W. RUSSELL (on behalf of Mr. BIRRELL) replied: Under regulations issued by the Department of Agriculture over 390 classes had been held in which over 10,000 pupils in all were enrolled. Of these classes, 304 were in first-aid to the injured, 179 in hygiene and emergency nursing, and 8 in ambulance work. The department do not regard the formation of classes in these subjects as any longer a matter of urgency, and accordingly they have since Dec. 31st last required that, except in very exceptional circumstances, classes should be recognised only if conducted under the conditions of a local scheme of technical instruction. If a technical instruction committee agrees to form such classes the department recognise them as eligible for grants under the conditions of their programme for technical schools and classes.

MONDAY, FEB. 22ND.

Release of Medical Non-combatants.

Replying to Lord ROBERT CECIL, Mr. PRIMROSE (Under Secretary for Foreign Affairs) said: An arrangement has been made with the German Government for the mutual release of civilian doctors, and negotiations are now in progress for the mutual release of medical officers of the military and naval forces. In a note to the United States Ambassador of Dec. 31st last H.M.'s Government offered to release the German medical personnel on condition of reciprocity, and we hope that an agreement on this subject will shortly be reached.

Insecticides on Imported Fruit.

Sir WALTER ESSEX asked the Parliamentary Secretary to the Board of Agriculture whether he had recently had complaints of the arrival from overseas of cargoes of apples upon which traces of poisonous insecticides were found, and, if so, in how many cases; whether close observation was being made upon incoming deliveries; and were steps being taken to prevent danger to public health from this source.—Sir HARRY VERNEY answered: No complaints have been made to the Board as to the presence of insecticides on imported fruits. Two cases were, however, brought to their notice last year of the presence of a fungicide, but the amount of the latter was unimportant. The matter is not one with which the Board are empowered to deal, but they published a note in their Journal for June, 1914, warning growers to remove all traces of sprays before marketing their fruit.

TUESDAY, FEB. 23RD.

The Production of Drugs.

Sir J. D. REES asked the Secretary to the Treasury whether the Government proposed to take special steps to facilitate the use of alcohol for commercial purposes in order to create favourable conditions for competition with Germany in the production of fine drugs.—Mr. ACLAND replied: So far as can at present be seen, there is no reason to suppose that the facilities available under the existing law are inadequate for this purpose.

WEDNESDAY, FEB. 24TH.

Spotted Fever in Essex.

Mr. ALDEN asked the Under Secretary for War whether he was aware that spotted fever had broken out in some parts of Essex; whether, under the circumstances, he would give special orders that the billeting carried out in all such districts should be done as carefully as possible and due precaution taken against overcrowding; and whether the local sanitary authorities were in all cases consulted before soldiers were billeted in large numbers.—Mr. TENNANT replied: I regret to say that spotted fever has broken out in some parts of Essex. Special orders have been issued with regard to billeting, and due precautions are being taken against overcrowding. The local sanitary authorities are consulted in all cases.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

BURLAND, J. A., L.R.C.P. & S. Irel., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Paignton District of the county of Devon.
HENNESSY, D., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Medical Adviser to the Irish Insurance Commissioners in Bandon and Murragh Dispensary Districts.
HOWIE, MARY E., M.B., B.S. Durh., has been appointed School Medical Inspector under the Aberdare Education Authority.
LYND, J. C., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer to the Limavady Post Office and Subdistrict Offices.
NICHOLSON, BALFOUR S., M.B., C.M. Glasg., has been appointed Tuberculosis Officer for Derby County.
SHARPE, FREDERICK A., M.D. Lond., has been appointed Medical Officer of Health of Barnsley.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

AYLESBURY, ROYAL BUCKINGHAMSHIRE HOSPITAL.—House Surgeon, unmarried, Salary £150 per annum, with board, washing, and lodging.
BARROW-IN-FURNESS, NORTH LONSDALE HOSPITAL.—House Surgeon, Salary £150 per annum, with residence, board, and laundry.

- BIRKENHEAD BOROUGH HOSPITAL.**—Senior House Surgeon. Salary £120 per annum, with board and laundry. Also Junior House Surgeon. Salary £100 per annum, with board and laundry.
- BIRMINGHAM CITY MENTAL HOSPITAL, Rubery-hill.**—Female Junior Assistant Medical Officer. Salary £200 per annum, with apartments, board, laundry, &c.
- BIRMINGHAM, YARDLEY-ROAD SANATORIUM AND ANTI-TUBERCULOSIS CENTRE.**—Third Assistant Medical Officer. Salary £200 per annum, with board and residence.
- BLACKBURN AND EAST LANCASHIRE ROYAL INFIRMARY.**—House Surgeons, Senior and Junior. Salary £150 and £130 per annum, with board, residence, and laundry.
- BOLTON UNION.**—Resident Assistant Medical Officer for Townleys Hospitals at Farnworth, near Bolton. Salary £250 per annum, with apartments, washing, and attendance.
- BOOTLE BOROUGH HOSPITAL.**—Junior House Surgeon. Salary £100 per annum, with residence, board, and laundry.
- BRISTOL EYE HOSPITAL.**—House Surgeon. Salary £100 per annum, with board, residence, and laundry.
- BRISTOL GENERAL HOSPITAL.**—Resident Obstetric Officer for six months. Salary at rate of £120 per annum, with board, residence, &c.
- BROADMOOR STATE CRIMINAL LUNATIC ASYLUM, Crowthorne, Berks.**—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, rooms, washing, and attendance.
- BURNLEY, VICTORIA HOSPITAL.**—House Surgeon. Salary £135 per annum, with residence, board, and washing.
- BURSELEM, HAYWOOD HOSPITAL.**—Female Resident Medical Officer. Salary £100 per annum, with board, residence, and laundry.
- BURY INFIRMARY.**—Junior House Surgeon. Salary £150 per annum, with board, residence, and washing.
- CAMBERWELL, CONSTANCE-ROAD INSTITUTION, East Dulwich, S.E.**—Temporary Resident Medical Officer. Salary at rate of £300 per annum, with apartments, board, and washing.
- CANTERBURY, KENT COUNTY ASYLUM, Chatham.**—Third Junior Assistant Medical Officer. Salary £250 per annum, with quarters, board, washing, &c.
- CANTERBURY MENTAL HOSPITAL.**—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, lodging, washing, and attendance. Also Locum Tenent Assistant Medical Officer for about a fortnight. Salary £8 6s. per week, with board, lodging, washing, and attendance.
- CANCER HOSPITAL, Fulham-road, S.W.**—House Surgeon for six months. Salary £100 per annum.
- CARMARTHEN, JOINT COUNTIES ASYLUM.**—Temporary Second Assistant Medical Officer. Salary at rate of £200 per annum, with board, lodging, washing, &c.
- CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.**—Resident House Surgeon. Salary £50 per annum, with board and residence.
- CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.**—Third Honorary Anesthetist.
- CROYDON GENERAL HOSPITAL.**—Honorary Radiographer.
- DARLINGTON HOSPITAL AND DISPENSARY.**—House Surgeon. Salary £150 per annum, with board, attendance, and laundry.
- DEVONPORT ROYAL ALBERT HOSPITAL.**—House Surgeon, unmarried. Salary £150 per annum, with board and laundry.
- DUDLEY, GUEST HOSPITAL.**—Senior Resident Medical Officer. Also Assistant House Surgeon for six months. Salary £150 and £120 per annum respectively, with board, residence, attendance, and washing.
- DUMFRIES AND GALLOWAY ROYAL INFIRMARY.**—Female Resident House Surgeon. Salary £120 per annum.
- EAST HAM BOROUGH EDUCATION COMMITTEE.**—Temporary Assistant School Medical Officer. Salary £300 per annum.
- EAST HAM, COUNTY BOROUGH OF.**—Tuberculosis Officer. Salary at rate of £500 per annum.
- ECCLLES AND PATRICKROFT HOSPITAL.**—House Surgeon, unmarried. Salary £70 per annum, with board, lodging, and washing.
- EDMONTON UNION INFIRMARY, Bridport-road, Upper Edmonton.**—Second Assistant Medical Officer, unmarried. Salary £200 per annum, with residential allowances.
- ESSEX EDUCATION COMMITTEE.**—Temporary Female School Medical Inspector. Salary £300 per annum.
- FIJI (THE GILBERT AND ELLICE ISLANDS PROTECTORATE AND THE SOLOMON ISLANDS PROTECTORATE).**—Three Medical Officers. Salary £350 per annum, free quarters provided.
- GLASGOW, GOVAN DISTRICT ASYLUM, Hawkhead, Cardonald.**—Senior Assistant Medical Officer. Salary £250 per annum, with board, apartments, and laundry.
- GREAT YARMOUTH HOSPITAL.**—House Surgeon, unmarried. Salary £200 per annum, with board, lodging, and washing.
- HALIFAX ROYAL INFIRMARY.**—Second and Third House Surgeons, unmarried. Salary £120 and £100 per annum respectively, with residence, board, and washing.
- HAMMERSMITH INFIRMARY AND WORKHOUSE, Ducane-road, Wormwood Scrubs, W.**—Assistant Medical Officer and Second Assistant Medical Officer. Salary £180 and £170 per annum respectively, with board, lodging, washing, and attendance.
- HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.**—Assistant Casualty Medical Officer, unmarried, for six months. Salary £30, with board, residence, &c.
- HULL, CITY AND COUNTY OF KINGSTON-UPON-HULL.**—Temporary Senior Tuberculosis Medical Officer. Salary at rate of £500 per annum.
- HULL, VICTORIA CHILDREN'S HOSPITAL, Park-street.**—Resident House Surgeon and Resident Assistant House Surgeon. Salary £60 and £50 per annum respectively, with board and laundry.
- LEICESTER ROYAL INFIRMARY.**—House Physician. Salary at rate of £120 per annum.
- LIVERPOOL, ROYAL SOUTHERN HOSPITAL.**—Three House Surgeons and Two House Physicians, each for six months. Salary at rate of £60 per annum, with board and residence.
- LIVERPOOL, WEST DERBY UNION, MILL-ROAD INFIRMARY.**—Two Temporary Assistant Resident Medical Officers, unmarried. Salary at rate of £300 per annum each, with board, &c.
- LONDON FEVER HOSPITAL, Liverpool-road, N.**—Assistant Resident Medical Officer. Salary £250 per annum, with residence and board.
- LONDON HOSPITAL, E.**—Assistant Surgeon.
- MANCHESTER, COUNTY ASYLUM, Prestwich.**—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, attendance, and washing.
- MANCHESTER, HULME DISPENSARY, Dale-street, Stretford-road.**—House Surgeon. Salary £180 per annum, with apartments, attendance, coal, and gas.
- MANSFIELD AND DISTRICT HOSPITAL.**—House Surgeon. Salary £200 per annum, with apartments, board, and laundry.
- MELTON, SUFFOLK DISTRICT ASYLUM.**—Second Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, attendance, and laundry.
- METROPOLITAN ASYLUMS BOARD: INFECTIOUS HOSPITALS SERVICE.**—Assistant Medical Officers. Salary £250 per annum, with board, lodging, and washing.
- MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.**—Senior House Surgeon for six months. Salary £100 per annum, with board, residence, and laundry.
- NEWPORT (MON.), ROYAL GWENT HOSPITAL.**—Resident Medical Officer. Salary for first six months at rate of £103 per annum, second six months £125, and third six months £150, with board, residence, and laundry.
- NORFOLK EDUCATION COMMITTEE.**—Assistant Medical Officer. Salary £300 per annum.
- NOTTINGHAM GENERAL HOSPITAL.**—Assistant House Physician for six months. Salary at rate of £100 per annum, with board, residence, and laundry.
- NOTTINGHAM, NOTTS COUNTY COUNCIL.**—Second Assistant Tuberculosis Officer. Salary £400 per annum.
- PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.**—House Surgeon. Salary at rate of £30 per annum, with board, residence, and washing.
- PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.**—Honorary Physician to the Skin Department.
- ROYAL DENTAL HOSPITAL OF LONDON, Leicester-square.**—House Anesthetist. Salary £60 per annum.
- ROYAL EYE HOSPITAL, Southwark.**—House Surgeon. Board and quarters, &c.
- ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London, E.C.**—Resident Medical Officer for six months. Salary at rate of £120 per annum, with board, lodging, and washing.
- ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, S.E.**—Second Resident Medical Officer. Salary at rate of £100 per annum, with board and washing. Also Temporary Honorary Assistant Physician to Out-patients.
- ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM, City-road, E.C.**—House Surgeon. Salary £100 per annum, with board, lodging, and washing.
- ST. MARY ISLINGTON INFIRMARY, Highgate Hill, N.**—Junior Assistant Medical Officer. Salary at rate of £140 per annum, and all found.
- ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.**—Junior Resident Medical Officer. Salary at rate of £90 per annum, with board, residence, and laundry.
- SALFORD ROYAL HOSPITAL.**—Casualty House Surgeon. Salary at rate of £100 per annum, with board and residence.
- SALFORD UNION INFIRMARY, Hope, Pendleton.**—Medical Superintendent. Salary £500 per annum, &c.
- SALISBURY GENERAL INFIRMARY.**—House Surgeon and Assistant House Surgeon, unmarried. Salary £100 and £75 per annum respectively, with apartments, board, lodging, and washing.
- SERBIAN RELIEF FUND.**—Physicians required.
- SHEFFIELD CHILDREN'S HOSPITAL.**—House Surgeon. Salary £150 per annum, with board and residence.
- SHEFFIELD ROYAL HOSPITAL.**—Female Assistant House Surgeon and Female Assistant House Physician. Salary £85 and £80 per annum respectively, with board, residence, and washing.
- SHEFFIELD ROYAL INFIRMARY.**—House Surgeon and Assistant House Physician. Salary £100 per annum, with board and residence.
- SHERWSBURY, ROYAL SALOP INFIRMARY.**—House Physician. Salary at rate of £110 per annum, with board and apartments.
- SOUTH AFRICA, PRERE HOSPITAL, East London.**—Resident Medical Officer, unmarried. Salary £300 per annum, with board, lodging, and washing.
- SOUTH LONDON HOSPITAL FOR WOMEN.**—Female Assistant Physician.
- SOUTH SHIELDS, INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTON DISPENSARY.**—Junior House Surgeon. Salary £115 per annum, with residence, board, and washing.
- STOCKPORT INFIRMARY.**—Junior House Surgeon. Salary £100 per annum, with board, washing, and residence.
- SUNDERLAND ROYAL INFIRMARY, CHILDREN'S HOSPITAL.**—Female Resident Medical Officer for six months. Salary £100 per annum, with board, residence, and laundry.
- SWANSEA UNION INSTITUTION.**—Resident Assistant Medical Officer. Salary £295 per annum.
- TAUNTON AND SOMERSET HOSPITAL, Taunton.**—Senior House Surgeon. Salary £120 per annum, with board, lodging, and laundry.
- TRURO, ROYAL CORNWALL INFIRMARY.**—House Surgeon, unmarried. Salary £150 per annum, with rooms, board, and washing.
- VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.**—House Physician and House Surgeon for six months. Salary £40 each, with board and lodging.
- WAKEFIELD CLAYTON HOSPITAL.**—Female Junior House Surgeon. Salary £120 per annum, all found.
- WARRINGTON INFIRMARY AND DISPENSARY.**—Senior House Surgeon. Salary at rate of £200 per annum, with board, apartments, and laundry.
- WARRINGTON, LANCASHIRE COUNTY ASYLUM, Winwick.**—Locum Tenens Medical Officer, unmarried. Salary 6 guineas per week, with apartments, board, attendance, and washing.
- WARWICK COUNTY LUNATIC ASYLUM.**—Temporary Assistant Medical Officer. Salary £6 6s. per week, with board, &c.
- WEI-HAI-WEI COLONY.**—Medical Officer. Salary £300 per annum, with free unfurnished quarters, &c.
- WEST BROMWICH AND DISTRICT HOSPITAL.**—House Surgeon and Assistant House Surgeon, unmarried. Salary £150 and £120 per annum respectively, with residence, board, and laundry.
- WESTMINSTER HOSPITAL, S.W.**—Qualified Medical Men who are able and willing to do so to volunteer their help.
- WEST HAM AND EASTERN GENERAL HOSPITAL, Stratford, E.**—Junior House Surgeon. Salary at rate of £100 per annum, with board, residence, and washing.

WEST RIDING OF YORKSHIRE, CARDIGAN SANATORIUM, near Wakefield.
—Assistant Medical Officer. Salary £300 per annum, with partial board.

WEST RIDING OF THE COUNTY OF YORK, SCALEBOR PARK ASYLUM, Burley-in-Wharfedale.—Assistant Medical Officer. Salary £250 per annum, with rooms, board, attendance, and washing. Or Locum Tenens. Salary £5 5s. per week.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY.—House Surgeon. Salary £150 per annum, with board, lodging, and attendance.

WIGAN, ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY.—Female Junior House Surgeon. Salary £130 per annum, with board, apartments, and washing.

YORK DISPENSARY.—Resident Medical Officer. Salary £200 per annum, with board, lodging, and attendance.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Downpatrick, County Down; at Enniskillen, County Fermanagh; and at Milford, in the county of Hampshire.

Births, Marriages, and Deaths.

BIRTHS.

CAMERON.—On Feb. 17th, at St. Thomas's-street, S.E., the wife of H. C. Cameron, M.D., a daughter.

HUSSEY.—On Feb. 19th, at Castle-street, Farnham, Surrey, the wife of James Hussey, M.D., of a daughter.

MARRIAGES.

PITT—WATKINS.—On Feb. 11th, at St. Peter's Church, Earley, Berks, Robert Cecil Pitt, M.R.C.S., L.R.C.P., to Beatrice Irene, only daughter of Mr. and Mrs. Alric Watkins, of The Traddock, Austwick, Yorkshire.

DEATHS.

FOGERTY.—On Feb. 14th, at George-street, Limerick, George Joseph Fogerty, Staff Surgeon, R.N.

HARPER.—On Feb. 16th, at Batheaston, Charles Harper, M.R.C.S., L.R.C.P., late Surgeon R.N., aged 87 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Air, Water, and Food from a Sanitary Standpoint. By Alpheus G. Woodman and John F. Norton. Fourth edition, revised. Price 8s. 6d. net.

Notes, Short Comments, and Answers to Correspondents.

"OF GOOD REPORT."

DURING the past week a number of medical men in different parts of England have forwarded for our information copies of a circular letter and enclosures which they have received through the post from the secretary of Winox, Ltd., 66, London Wall, E.C. The object of these communications is to bring the claims of "Winox Wine Food" before members of the medical profession. The secretary's letter begins as follows:—

In requesting you to read the enclosed Clinical Reports we feel we are only asking what is due to you, to us, and to your patients, especially those recovering from wounds, operations, or sickness resulting from the War.

And concludes thus:—

We ask you to give "Winox Wine Food" a trial, and are willing to pay you three guineas for a report on the results in three or more cases. We do not require or expect that all these trials will be entirely favourable "Winox" is no "panacea" but from the reports we send you we feel confident that a very large majority of such trials must be satisfactory, and on these grounds will pay for all without distinction. Will you let us know how many bottles we may send you for the purpose of this investigation?

The enclosures consist of a postcard, to be filled in by the medical man, asking for samples of the preparation and agreeing to test and report upon them; a pamphlet entitled "20 Clinical Reports on Winox Wine Food" and marked "not for general publication," and an additional signed report by a medical man, describing himself as "Civilian Surgeon, R.A.M.C., &c.," upon three wounded soldiers from the front who each made a good recovery after the administration of this substance. The pamphlet contains 20 signed letters from medical practitioners testifying to the value of Winox Wine Food, and after each signature is printed an extract from the Medical Directory, 1914, while the last two pages contain appreciations from nurses and from members of the public. With the scientific value or otherwise of these testimonials we are not here concerned, but the distribution of them to other practitioners, in conjunction with an offer of 3 guineas each for further reports, is serious. The proprietors of Winox, by the wording of their secretary's letter, have no doubt protected themselves against a direct charge of bribery, and we do not suggest that the proffered fee would be withheld in the event of an adverse report. But we regard the procedure as a most undesirable innovation in methods of advertisement, while the medical men whose reports accompany the circular are inviting, and indeed receiving, unfavourable comment from their professional brethren. They should at once make their position clear. Have they, or any of them, had the fee for their reports?

WANTED, A HOME.

To the Editor of THE LANCET.

SIR,—Perhaps one of your readers could help me. I want to find a home for a girl who is weak mentally and a kleptomaniac. She is not certifiable. Her parents could pay about £1 per week. I am quite out of touch with these matters, and I know people have occasionally obtained valuable help from your correspondents.

I am, Sir, yours faithfully,

Feb. 16th, 1915.

C. A. J.

THE NATIONAL LEAGUE FOR PHYSICAL EDUCATION AND DEVELOPMENT.

THIS league, which is now amalgamated with the Mansion House Council on Health and Housing, in its ninth annual report for the year ending October, 1914, shows that considerable gain in efficiency has been made and overlapping reduced by its coöperation with many other bodies having allied aims—the National Association for the Prevention of Infant Mortality, the National Society of Day Nurseries (which gained for the latter recognition of the Board of Education and State financial aid), the Child Welfare Bureau of the Social Welfare Association, the Voluntary Central Health Committee for London, and many others. The report this year omits the branch reports on economic grounds, but it contains that of the Mansion House Committee on Health and Housing. Last year's comprehensive report on school clinics at home and abroad has led to a large increase in these institutions during the past year. A separate included report is that of the Association of Infant Consultations and Schools for Mothers, the list of affiliated societies of which occupies nearly three pages of small type. Its

report, which is signed by Dr. Eric Pritchard as chairman, and the Hon. Eleanor Ritchie as honorary secretary, shows the work done in mothercraft competitions and in other ways. There are some excellent leaflets and pamphlets published by the league, among which may be specially mentioned Hints on the Management of Children from 1 to 5 Years of Age, and a telling poster illustrating in three pictures a bad way, a better way, and the best way of feeding infants. As to more important publications, the excellent little book entitled "Mothercraft" was reviewed in THE LANCET, Feb. 13th, 1915, p. 333.

The address of the league, which has on its council Sir Clifford Allbutt, Sir William Osler, Sir Lauder Brunton, Sir John Tweedy, Sir Rickman Godlee, with many other representative members of the medical profession, is 4, Tavistock-square, London, W.C.

CENTIGRADE INTO FAHRENHEIT.

To the Editor of THE LANCET.

SIR,—Having experienced some difficulty in converting Centigrade degrees into Fahrenheit, I have solved the question, personally, by a simple plan. Centigrade 0° equals Fahrenheit 32°, freezing point. Each degree of Centigrade upwards requires an addition of 1.8° Fahrenheit. Taking, for example, 20° Centigrade, the equivalent of Fahrenheit is found by multiplying the 20° Centigrade by 1.8° Fahrenheit. This gives 36° Fahrenheit. Add to this the starting-point, 32° Fahrenheit, the result is 68° Fahrenheit. In the minus scale of Centigrade the 1.8° Fahrenheit is deducted. Example: —15° Centigrade requires 15 times 1.8° Fahrenheit, equals 27°. Deduct this from 32° Fahrenheit and the result is +5° Fahrenheit.

There are only two factors to be remembered, that 0° Centigrade is equivalent to 32° Fahrenheit, and that each degree of Centigrade requires 1.8° of Fahrenheit to be added or deducted as the plus or minus scale is applied.

I am, Sir, yours faithfully,

Feb. 23rd, 1915.

QUATORZE, M.D.

FIRES DUE TO AIR RAIDS.

THE British Fire Prevention Committee has issued a circular containing some useful directions as to what to do in the event of a fire breaking out due to an air raid. The precautions enjoined are for the most part applicable to outbreaks of fire from other causes, and are such as would be adopted by sensible persons in any case. Free copies of the circular may be had by applying to the offices of the committee, 8, Waterloo-place, Pall Mall, London, S.W.

WEIGHT AND MEASUREMENTS OF GERMAN SOLDIERS.

A CORRESPONDENT writing on the physical measurements of soldiers points out that the average weights and heights of German adult men who in time of peace were considered fit for military service by the army medical authorities were as follows: average height, 166 cm. (5 ft. 5.3 in.); average weight, 65 kg. (10 st. 3.3 lb.); chest measurement, taken with the arms evenly extended, close under the nipples in front and close under the angles of the shoulder-blades behind, average inspiration, 89 cm. (35 in.), and average expiration, 82 cm. (32.3 in.), showing a maximum difference between inspiration and expiration of 7 cm. (2.7 in.); girth, taken 1 cm. above the umbilicus, 75 cm. (29.5 in.). It might be interesting to know how far these standards are being maintained at the present time among the new levies for the German army.

A SUSSEX MEDICAL MAN'S GOLDEN WEDDING.

Dr. G. A. Jeffery and Mrs. Jeffery, of Hailsham, celebrated their golden wedding on Feb. 21st, and received numerous messages of congratulation. The marriage ceremony took place at Upper Clapton, and of the six bridesmaids no fewer than five are still living. A Cornishman by birth, Dr. Jeffery has resided in Sussex for 60 years, and for half a century practised at Eastbourne, where he also held a number of public appointments. On relinquishing work, Dr. Jeffery removed to Hailsham, not far from Eastbourne, and despite his great age—he is in his 91st year—is able to continue his active interest in local affairs. He is an alderman and justice of the peace for East Sussex.

RUBBER HEELS.

M. S.—There is, we believe, no evidence available of any connexion between the use of hard leather-heeled boots and diseases of the spinal column or nervous system, despite the unnaturally hard surfaces on which millions of us spend our lives. The central nervous system is so jealously guarded by muscles, intervertebral discs and cerebro-spinal fluid, and meninges and ligaments, that it habitually withstands far greater shocks than hard heels are capable of inflicting. The joints and bones of the skeleton are also protected by muscles, cartilages, and ligaments. It is, however, conceivable that boot heels of soft material may be of service in softening jars to inflamed joints—in chronic

arthritis, for instance; but the end is better secured by placing a layer of spongy indiarubber inside the boot rather than outside. What H. J. Byron called "the midnight footfall of the peeler on his beat" is no doubt usefully muffled by indiarubber heels and soles.

F. H. B.—In Continental States, where the metric system is now generally adopted for the dispensing and preparing of medicines, all liquids are weighed, and the terms gramme, centigramme, and kilogramme only are used. This avoids the possibility of errors, which the similarity of the names decagramme and decigramme might lead to.

Falstaff.—Honey contains approximately 70 per cent. of the sugars known as levulose and dextrose in about equal proportions. Fruits contain the same sugars, but in smaller proportion.

R. H.—It is most unsatisfactory to advise without examination. We should suggest varying the sulphate of magnesia by prescribing 3 ss. of pure petroleum every night.

Radium.—There is no scientific reason why a water of permanent radio-activity should not be prepared.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Papers:—Prof. W. A. Bone, Prof. H. L. Callendar, and Mr. H. J. Yates: A Bolometric Method of Determining the Efficiency of Radiating Bodies.—Mr. E. Chappell: The Simplification of the Arithmetical Processes of Involvement and Evolution (communicated by Prof. W. B. Dalby).—Mr. F. E. Rowett: The Elastic Properties of Steel at Moderately High Temperatures (communicated by Prof. B. Hopkinson).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

WEDNESDAY.

SECTION OF OPHTHALMOLOGY (Hon. Secretaries—Leslie Paton, Elmore W. Brewerton): at 8.30 p.m.

Cases (at 8 p.m.)

Papers:

Mr. Leslie Paton: The Montessori System and its Use for Children with Defective Sight.

Mr. Bishop Harman: The Education of Children with Defective Vision.

Mr. J. H. Fisher: Retinitis in Pregnancy.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.—The Members of this Section are specially invited to attend the discussion on the first two papers at the meeting of the Section of Ophthalmology. (See above.)

THURSDAY.

SECTION OF BALNEOLOGY AND CLIMATOLOGY (Hon. Secretaries—Charles W. Buckley, J. Campbell McClure): at 5.30 p.m.

Paper:

Dr. Leonard Williams: The Teutonic Health Resorts and their Substitutes.

NOTE.—Members of other Sections are invited.

SECTION OF MEDICINE.—Members of the Section of Medicine are specially invited to attend the meeting of the Section of Balneology and Climatology. (See above.)

SECTION OF SURGERY.—Members of the Section of Surgery are specially invited to attend the meeting of the Section of Balneology and Climatology. (See above.)

FRIDAY.

SECTION OF LARYNGOLOGY (Hon. Secretaries—Cecil I. Graham, W. D. Harmer): at 4 p.m.

Cases and Specimens:

Will be shown by the following:—Dr. William Hill, Mr. Secombe Hett, Sir William Milligan, Mr. Cecil Graham.

Dr. Pegler: Specimens of Superior Maxilla, illustrating Abnormal Antra and Nasal Fosse.

SECTION OF ANÆSTHETICS (Hon. Secretaries—Cecil Hughes, F. B. Shipway): at 8.30 p.m.

Discussion:

On the Influence of Preliminary Narcotics on the (a) Induction, (b) Maintenance, (c) After-results of Anæsthesia (to be opened by Dr. J. Blumfeld).

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 p.m., Paper:—On the Outbreak of Toxic Jaundice of a New Type among Aeroplane Workers—(a) Clinical and Toxicological Portion by Dr. W. H. Wilcox, (b) Pathological Portion by Dr. B. H. Spilsbury, (c) Industrial Aspects by Dr. T. M. Legge.

RÖNTGEN SOCIETY, Institution of Electrical Engineers, Victoria Embankment, W.C.

TUESDAY.—8.15 p.m., General Meeting. Paper:—Mr. A. Fleck: The Chemistry of the Radio Elements.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 p.m., Clinical Meeting.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, Society's Rooms, West London Hospital, Hammersmith-road, W.

FRIDAY.—8.30 p.m., Paper:—Dr. R. Morton: The X Ray Appearances of Some Common Disorders of the Stomach (with lantern slides).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY, WEDNESDAY, AND FRIDAY.—5 P.M., Hunterian Lectures:—Prof. A. Keith: The Anatomy and Mechanism of the Alimentary Canal. (Illustrated by specimens from the Museum of the College and by the use of the epidiascope.) (Lectures IV., V., and VI.)

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. E. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 11 A.M., Mr. Souttar: Demonstration of Minor Operations. 12 noon, Lecture:—Mr. Souttar: Abdominal Diagnosis. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 12 noon, Lecture: Dr. G. Stewart: Neurological Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynaecological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. Bernstein: Applied Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 12 noon, Lecture:—Mr. Souttar: Surgical Anatomy of the Abdomen. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics.—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipple). Gynaecological (Dr. J. B. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Operations. Clinics.—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. Howell Evans); Nose, Throat, and Ear (Mr. H. D. Gillies). X Rays and Electrical Methods (Dr. Metcalfe). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Special Lecture:—Mr. T. H. C. Beulans: The Diagnosis of Disease by Clinico-pathological Methods (with illustrative cases).

WEDNESDAY.—Clinics.—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipple); Skin (Dr. G. N. Meschen); Eye (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynaecological Operations (Dr. A. E. Giles). Clinics.—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson); X Rays and Electrical Methods (Dr. Metcalfe).

FRIDAY.—2.30 P.M., Operations. Clinics.—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—4 P.M., Dr. C. R. Kempster: X Rays. Rodent Ulcer.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Common Hypertrophies.

MANCHESTER HOSPITALS POST-GRADUATE CLINICS.

THURSDAY.—ANCOATS HOSPITAL, Mill-street.—4.30 P.M., Dr. D. E. Core: Parasyphilis.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1914 were given in THE LANCET of Dec. 26th, 1914.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1914 are now ready. Bound in cloth, gilt lettered, price 16s., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.			TO THE COLONIES AND ABROAD.		
One Year	...	£1 1 0	One Year	...	£1 5 0
Six Months	...	0 12 6	Six Months	...	0 14 0
Three Months	...	0 6 6	Three Months	...	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET OFFICES, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Hunterian Lecture

ON

THE OPERATIVE TREATMENT OF CLEFT PALATE.

Delivered before the Royal College of Surgeons of England on Feb. 17th, 1915.

By H. BLAKEWAY, M.S. LOND., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR AT THE COLLEGE; SURGICAL REGISTRAR, ST. BARTHOLOMEW'S HOSPITAL; SURGEON, WITH CHARGE OF OUT-PATIENTS, VICTORIA HOSPITAL FOR CHILDREN; ACTING ASSISTANT SURGEON, ROYAL FREE HOSPITAL.

MR. PRESIDENT, LADIES AND GENTLEMEN,—My first duty is to express my thanks for the privilege of addressing you to-day; and this I do, esteeming this Hunterian professorship not only as an honour but also as a responsibility the extent of which may be gauged by reference both to the conditions of its foundation and to the fame of those who have in former times sustained it.

INTRODUCTION.

The subject of the treatment of cleft palate has been during recent years the occasion of hot dispute; such a condition of things reveals a dissatisfaction with existing modes of treatment, and an inability on the part of the practitioners of any one form of operation to show it as certainly superior to other methods.

Convinced as I am of the necessity of knowledge as to the results of treatment, much of this lecture will be devoted to discussion of this part of the subject: a part which could not have been investigated at all without the help of those who have so generously allowed me to record the results of their operations. To all these gentlemen I tender my most grateful thanks.

THE OPERATION OF "MEDIAN SUTURE."

Historical.

The operative treatment of cleft palate is 150 years old. It is said that Le Monnier sutured with success a complete fissure of the palate as early as 1764 (he has himself left no record of the operation, but the account given by Robert¹ is sufficiently circumstantial), and that in 1816 von Graefe cured a cleft of the soft palate, while Ebel operated unsuccessfully a year later.² Roux's famous first staphylorrhaphy occurred in 1819,³ and a few years later Warren, of Boston, independently performed the operation with success.⁴

In this country Fergusson in 1844⁵ was the first deliberately to base his operation upon anatomical foundations. With the advantage gained by a dissection of the muscles of a cleft palate in an adult he successfully divided certain of those muscles so as temporarily to relieve the halves of the palate from their traction. His method was immediately adopted by others.

About this time clefts of the hard palate also began to be attacked by operation. Dieffenbach in 1834⁶ appears to have been the first to separate the soft parts from the underlying bone, and drawing them inwards, to suture them in the middle line. Mason Warren⁷ in America used the same plan, which was tried in England by Fergusson⁸ and by Pollock.⁹ These surgeons probably used the whole thickness of the soft parts to form their flaps, though they seem to have been under the impression that the mucous membrane only was detached. No. 4775.

Warren specially mentions that the mucosa is rather peeled than dissected off; and the mucoperiosteum is an indivisible structure, without distinction of mucous and submucous layers.

By the middle of the last century, therefore, were already known and practised most of the steps of the operation of median suture nearly as we see it to-day. It was left to Langenbeck¹⁰ in 1862 to raise flaps in which the periosteum was deliberately included, to collect the scattered writings of Europe and America, and to describe in consecutive detail the steps of an operation which has since borne his name. His paper marks an epoch in the history of the surgery of cleft palate.

The operation as now performed differs in only two essentials from Langenbeck's practice—it is performed at a much earlier age, and almost always with the aid of a general anaesthetic. For both of these advances we are indebted to the late Sir Thomas Smith,¹¹ who urged in 1868 that the operation should be done, if possible, before the patient learns to speak, and who advocated the use of chloroform as the anaesthetic.

Such, briefly, is the history of Langenbeck's operation; if the details of its performance have varied the principles upon which it is based are the same, and the results of Fergusson and of Smith remain still admirable as examples of the best that can be obtained.

Results.

I propose now to describe the results of the operation in the hands of different surgeons.

Langenbeck¹² gives us details of his first 21 cases of congenital cleft palate, operated upon at ages varying from 7 to 29½ years. The results were as follows:—

(a) Among 14 cases of complete cleft of hard and soft palates 10 resulted in complete closure and only one was a complete failure. The effect upon the speech is noted in 9 of the cases in which complete closure occurred; the note varies from "slight improvement" to "perfectly distinct."

(b) Among 6 cases of cleft of the soft and part of the hard palate, complete closure resulted in 5 and incomplete closure in 1. Here the condition of the speech after operation was only noted in 1 case; it was "intelligible," having been completely unintelligible before the operation.

(c) In 1 case of cleft due to congenital absence of the left intermaxilla, complete closure was attained.

Most of these cases were operated upon more than once, closure of the soft palate being first attempted, and later that of the hard.

Sir Thomas Smith¹³ published the results of 51 cases treated by him; in any comparison of these results with those of other operators it must be borne in mind that very many of his cases were operated upon at an age much earlier than that at which the operation had previously been considered practicable; moreover, they were some of his earliest cases. The ages of these 51 patients varied from 2 to 29 years. The results were:—

(a) In 18 cases of complete cleft, complete closure occurred in 7, partial closure in 8, and complete failure in 3.

(b) In 27 cases of cleft of the soft and part of the hard palate, there resulted complete closure in 8, partial closure in 16, and failure in 3 instances.

(c) Complete closure was obtained in all of 6 cases of cleft of the soft palate only.

The effect upon the speech is noted in 7 cases only; in all of these the articulation was much improved.

Coming to more recent times the most important contribution to our knowledge has been made by Mr. Berry.¹⁴ The great value of his series of 154 cases depends upon the fact that not only is the immediate result of the operation given, but, with

20 exceptions, the patients have been traced, and the condition of the palate and of the speech noted at intervals varying up to 15 years after operation. It is worthy of attention, in view of the suggestion sometimes made that those who perform Langenbeck's operation do not see the worst cases of cleft palate, that only 31 of these cases presented a cleft of the soft palate alone, while in 60 the cleft was complete.

As regards closure of the cleft the results may be summarised as follows: Of the cases of complete cleft 73 per cent. obtained complete union, and none were utter failures; where the cleft involved the soft and a part of the hard palate, once again the percentage of cases of complete closure was 73, while the percentage of failures was only 3·4; lastly, in cases of cleft of the soft palate only, 87 per cent. were completely healed and 3·2 per cent. failed. The majority of these patients were operated upon only once. Many of them had previously undergone unsuccessful operations by other surgeons.

Table I. shows the results as regards the function of speech in all the cases in which a note of the effect upon the speech was made: it should be observed that by far the greater number of the cases reported were hospital patients, who received after the operation no skilled training in articulation. In arranging the table account has been taken, not only of the original extent of the cleft, but also of the age at which the first operation was performed.

TABLE I.—Classification of Speech of Patients in Dr. Berry's Series of 154 Cases (Langenbeck's Operation).

Age at which first operation performed	Good.			Fair.			Bad.		
	2 and under.	2-8 years.	Over 8 years.	2 and under.	2-8 years.	Over 8 years.	2 and under.	2-8 years.	Over 8 years.
Complete cleft... ..	5	12*	7	—	12†	2	—	5†	—
Cleft of soft and part of hard palate	1	10	11	2	15	5	—	2†	2
Cleft of soft palate... ..	3	6	—	—	6†	2	1	3†	—

* Three of these patients received careful training.
† These include several mentally deficient children.

In spite, therefore, of the disadvantage of lack of training good articulation was obtained in a large proportion of the cases. It is to be noted that of the patients under 2 years of age at the time of operation nearly all appear in the "good" column (a result partly attributable to the fact that early operations would be more likely to be performed upon the slighter cases of the deformity); on the other hand, it is evident that the prognosis as regards speech, in those cases in which the patient is not brought for operation until after he has acquired faulty habits of articulation, is not nearly so hopeless as is frequently stated.

Admirable as these results are, they have been objected to on the ground that they can only be achieved by very few possessed either of special skill or of great experience in the performance of the operation. I believe it to be true that the result of the operation depends more upon the individual skill of the surgeon than upon any other factor in the treatment; this individual skill consists neither in great manual dexterity nor in having performed large numbers of operations for cleft palate, but is in great part acquired by a careful preliminary study of the details of the operation and especially by watching its performance in the hands of those who are accustomed to it.

I have recorded elsewhere¹⁵ a series of what may be regarded as average results, obtained in 200 cases treated at St. Bartholomew's Hospital. Complete union was obtained in 31 per cent. of complete clefts, 57 per cent. of clefts involving only a part of the hard palate, and 69 per cent. of clefts of the soft palate.

Table II. shows the results of my own cases operated upon by Langenbeck's method; they are only 11 in number, but they illustrate the same point, that a considerable degree of success may be reached, without large personal experience, by

TABLE II.—Eleven Cases of Cleft Palate treated by Langenbeck's Operation.

No.	Sex and age.	Extent of cleft.	Operations.	Result.	Remarks.
1	F., 3	Complete; left harelip cured.	9/10/1911	Death under anæsthetic.	P.M. status lymphaticus.
2	F., 12	Soft, and half of hard palate.	26/10/1911	Posterior 2 inch healed.	Pyorrhœa alveolaris.
3	M., 15	Complete; left harelip cured.	13/11/1911 27/11/1911	Failed. Complete closure.	Secondary hæmorrhage 13th day. Pleurisy on 14th day.
4	M., 2	Complete; left harelip cured.	20/11/1912	Complete closure.	Small hole, left immediately after operation, closed spontaneously.
5	F., 14	Soft, and half of hard palate.	13/7/1914	Complete closure.	—
6	F., 13/12	Soft palate.	19/8/1914	Complete closure.	Previous operation at 6 months had failed.
7	F., 2 10/12	Complete; right harelip imperfectly cured.	24/8/1914	Complete closure.	Operation for improvement of lip, Sept. 16th.
8	F., 5	Soft, and greater part of hard.	31/8/1914	A hole, 5 mm. wide, at junction of hard and soft palates.	Previous unsuccessful operation at 4 years.
9	F., 1 1/2	Complete; left harelip cured.	23/9/1914	Failure.	Very wide cleft; anterior part could not be closed.
10	F., 2	Soft, and half of hard palate.	7/10/1914 6/1/1915	Hard palate only healed. Tiny hole in soft palate.	Bronchitis after second operation.
11	F., 5	Soft palate.	28/10/1914	Complete closure.	Previous unsuccessful operation at 18 months.

studying the methods of others. The first patient died under the anæsthetic when the operation had only been begun; of the remaining 10 cases, complete closure of the cleft was obtained after one operation in 6, 3 of which were cases of complete cleft. One case (No. 9) resulted in complete failure; the cleft was complete and very wide, extending forwards through the alveolar arch. This anterior part of the cleft could not be closed at the operation. Probably it would have been wiser to have waited longer before operating. In Case 2 I operated unwisely in the presence of pyorrhœa alveolaris; the wound suppurated, and only a small part of it united. An attempt a fortnight later to bring the edges together and to obtain union by granulation also failed.

THE "TURN-OVER FLAP" OPERATION.

I come next to the consideration of the turn-over flap operation, now known by the name of Sir Arbuthnot Lane. It differs radically from Langenbeck's method in that one, at any rate, of the

flaps raised from the oral surface of the palate is turned over like the page of a book, remaining attached along the edge of the cleft. The raw surface of the flap now looks downwards towards the mouth, and the mucous-membrane-covered surface upwards to the nasal cavity. In the case of the hard palate the flap consists of all the soft tissues, including the periosteum; its free edge is drawn under the muco-periosteum at the opposite side of the cleft, raised up from the bone for the purpose. In the region of the soft palate the flap includes only mucous membrane and submucous tissue, and is in part covered by a second flap turned across from the nasal surface of the opposite half of the velum.

History.

Flap operations more or less resembling this have been performed at various times since 1824, when Krimer³ operated in the case of a girl, aged 18, upon a cleft involving the soft and most of the hard palate; the greatest breadth of the cleft was nearly an inch. Two similar flaps were raised from the tissues upon either side of the cleft and were turned over towards the middle line and their edges sutured together, the raw surfaces of the flaps looking downwards into the mouth. Complete healing is said to have resulted. The after-history of the patient was not traced. Langenbeck met with no success in 2 cases in which he employed this operation. Nélaton and Blandin¹⁶ tried in the case of cleft of the soft palate procedures allied to the method of Sir Arbuthnot Lane. The former, having turned over a flap from one side of the cleft, comprising half the thickness of the soft palate, partly covered the raw surface of the flap by paring the opposite edge of the cleft in a bevelled fashion. The latter fashioned a flap from each side of the cleft and sutured the two flaps together.

In more recent years Davies-Colley¹⁷ devised a method in which hinged flaps sutured together had their raw surfaces covered by another flap slid over them from one of the sides of the palate.

It is not my intention to discuss any of these flap operations other than that advocated by Sir Arbuthnot Lane. Davies-Colley's method was not intended by its author for general use, and it is at the present time used by very few surgeons; and the other operations are now never performed.

Advantages Claimed for the Flap Operation.

It is necessary before recording the results of Lane's operation, which I propose to bring before you, to enumerate the claims that have been made in support of this method, and to see to what extent these claims have been made good. The chief of the advantages claimed for the method is the early age at which the operation can be performed: the day after birth is stated to be the most suitable time.¹⁸ Those who advocate operation in early infancy are as a rule supporters of the flap method, if for no other reason because Langenbeck's operation cannot, as a rule, be performed in the first weeks of life, whereas the flap method can be utilised, even at this early period, to close clefts of almost any width. It is even sometimes suggested that the worst cases of cleft palate cannot be successfully treated by any other operation.

Most of the other advantages claimed for the flap operation are stated to result from the possibility of performing it in early infancy. In the first place

the operation is said to be "life-saving." The originator of the method said as follows:—

Surgeons were satisfied to operate on but a very small proportion of the cases of bad cleft palate, since only a fraction of the number of such cases survived to the age at which the operation they recommended was performed—namely, four to six years. They did not seem to realise that the closing of the cleft in the hard palate was an operation of urgency in severe cases, and that it was a condition that called for immediate interference in order to save the life of the child.¹⁹

The belief that the flap operation is "life-saving" depends upon three minor beliefs: (1) that the mortality among children with bad cleft palate depends upon the fact that the infant cannot be fed; (2) that the successful performance of the operation makes feeding possible; and (3) that the mortality of the operative treatment is less than that among infants suffering with untreated cleft palate.

The first of these cannot be regarded as proved. There can be no doubt that many infants born with cleft palate do die of inanition, but it is likely that most of these deaths result either from unsuitable quality of the food or from ignorance of the means by which it should be given. The late Sir Thomas Smith stated that in newly born infants with cleft palate, with hare-lip, or with both, and in other respects healthy, he had never failed to secure a plentiful administration of nourishment.

Of course, if the condition of bad cleft palate does not make feeding impossible, then the second of the above-mentioned propositions loses its significance. A child with a cleft palate, however extensive, can swallow in normal fashion, and can therefore be made to take food by artificial means; a successful operation might enable it to take the breast, but it seems almost certain that by the time the wound in the palate is sufficiently healed to enable this method of feeding to be tried, the mother would no longer be able to feed the infant.

What is the mortality among infants with untreated cleft palates? The question will not be settled until definite figures are available, and in their absence it is evident that early operation for cleft palate ought not to be claimed to be a life-saving measure. It may even be, as has been suggested, that it is the reverse of life-saving, if the mortality of the operation itself is a high one.

Published Results.

The figures as to the death-rate of the operation differ in the experience of different surgeons.

The most important statistics available up to the present time are those given by Mr. Barrington-Ward²⁰ from cases treated at the Hospital for Sick Children, Great Ormond-street. Here, among 144 first operations on infants of 1 year of age and under, 18 resulted fatally—a mortality of 12.5 per cent. The mortality of secondary operations, as would be expected, is much less, though it cannot be exactly ascertained from the figures given.

Spencer²¹ refers to a series of 14 cases treated by Lane's method in early infancy; 4 of these had died. In 1 the death could not be attributed to the operation; of the other 3, 2 died from pneumonia, respectively 14 and 21 days after discharge, and the third from recurrent hæmorrhage.

Fagge²² states that of 38 infants under 1 year of age at the time of their first operation, "1 died during the palate operation and 2 died in hospital, but the remote mortality was much more alarming, for an effort to trace these patients by correspondence showed that 14 others had died from various causes, of which 6 were directly or indirectly due to subsequent operations for hare-lip." It is not definitely stated that all these cases were treated by the flap operation.

Goyder²⁴ records a series of 26 cases operated upon by Lane's method. Of the cases 13 were children up to 14 months old; of these infants, 1 died, as also 1 of the older cases. Many of the patients had the operation repeated more than once.

I recently had the opportunity of tracing the results at intervals after operation of from 6 months to 3½ years in 17 cases treated by this operation by Mr. Richard Warren. The ages of the patients at the time of the first operation varied from 12 days to 5 years, 11 of the children being under the age of 12 months. There were no deaths attributable to the operation.

All these results do not allow us to form final conclusions as to the question of mortality. It is unfortunate that Barrington-Ward's figures apparently only relate to cases dying whilst in hospital, whereas some of the other statistics show that deaths (some of which are attributable to the operation) may occur after the infants have returned home.

A factor which is certainly of great importance in determining the difference in the death-rate of the flap operation in the hands of different surgeons is the exercise or the non-exercise of selection among the cases. If early operation is regarded as necessary in all cases and as life-saving in ill-nourished infants no selection of cases will be made, and a series of cases treated in this way will show a mortality higher than would be the case if marasmic infants were looked upon as unfit subjects for operation.

If it be accepted that early closure of the cleft is of such great importance for preserving the life of the child, the claim that the early operation is life-saving depends, too, upon the prospect of closure of the cleft, especially in the bad cases. Up to the present it has been difficult to say, from any published statistics, what are the prospects that the cleft will be closed.

Goyder, in his series of 26 cases, obtained the following results:—

(a) Among 13 cases in infants up to 14 months:—

Complete closure after one or more operations	9
Partial closure	3
Failure (one operation only)	1

(b) Among 13 cases in patients over 14 months (7 of these patients were 12 years old or more):—

Complete closure after one or more operations	11
Partial closure	1
Failure (one operation only)	1

The value of these results is unfortunately lessened by the fear that some of them at any rate only represent what was achieved at the end of the operation—for example, 2 of the patients in whom "complete closure" was noted died, the one a month and the other only 20 minutes after the operation.

In the 17 cases already referred to, operated upon by Mr. Warren and traced by myself, the results were as follows:—

(a) In ten cases of complete cleft:—

Complete healing after one or more operations	3
Partial healing	7

In 1 case of complete healing and 1 of partial healing the result was taken from the hospital notes, the attempt to trace the patient having failed.

(b) In 7 cases of cleft of the soft and part of the hard palate:—

Complete healing after one or more operations	4
Partial healing	2
Complete failure after one operation	1

One of the two cases of partial closure was that of a child recently dead; the result is that given in the hospital notes.

The second great advantage that is stated to result from early operation is the more normal development of the palate and of the nose and nasopharynx in the early years of life, so that the

function of speech is likely to be better accomplished than in those in whom the operation has been deferred until a later date, even though in these latter the cleft may be closed before the child has learned to speak. The proof of this contention has been completely wanting. No large consecutive series of cases examined at a sufficient interval after operation has been published, and it seems fair to conclude from the published Proceedings that in the cases of the patients shown at a meeting of the Royal Society of Medicine in 1911, the alleged superiority of the flap operation was not shown.

I come to the last contention that has to be discussed—that there are cases of cleft palate which, on account of the great breadth of the cleft compared with that of the palatine tissue at the sides of it, can only be closed by a flap operation in early infancy, or by some attack upon the bones (such as the method of Brophy, to be mentioned later). The most direct reply to this statement has been made by Mr. Berry,²⁵ who has declared that he has never seen such a case, and that he would be grateful to anyone who would show him a case at the age of 2 or 3 years in which the cleft was too wide to be closed by a Langenbeck operation.

Evidently it is difficult for those who perform only the flap operation to advance direct proof of this claim in its favour. The suggestion has, however, often been made that a disproportionately large percentage of bad cases is met with by them, and available figures to some extent support this view. Barrington-Ward, for example, states that among 144 cases of cleft palate in infants operated on by Sir Arbuthnot Lane 53 per cent. showed complete clefts of both lip and palate; in 36 per cent. the hard palate, and in 11 per cent. the soft palate only was involved.

I have already mentioned that in Mr. Berry's series of 154 cases treated by Langenbeck's method, 60—i.e., 39 per cent.—were cases of complete cleft; and in 200 cases which I collected and which have been referred to the figures were as follows:—

Complete cleft of hard and soft palate	93 cases = 46.5 per cent.
Cleft of soft palate and part of hard	65 cases = 32.5 "
Cleft of soft palate only	42 cases = 21.0 "

In this series, therefore, the percentage of cases of complete cleft is not far short of that given by Mr. Barrington-Ward; and it is actually higher than the percentage in 100 cases operated upon by Sir Arbuthnot Lane, to be mentioned presently.

I have tried to review impartially such evidence as is available concerning the claims put forward on behalf of the flap operation. The evidence is remarkably little. The statement that the operation is life-saving has not been proved. That because of the overlapping of flaps and the absence of tension union is more easily secured than by the operation of median suture is suggested by Goyder's series of cases, but the series is a small one, and the details given are in several respects meagre. The suggestion that the worst cases of cleft palate can only be closed by a flap operation in early infancy is difficult of decision; it lacks proof, and it has been flatly denied by Mr. Berry, whose experience in the Langenbeck operation is probably second to none. Finally, the expectation that on account of the early age at which the operation can be done the speech will be much better than in cases where operation has been deferred to a later date has not yet, so far as can be shown, been realised.

(To be concluded.)

A CASE OF MULTIPLE PULSATING TUMOURS SECONDARY TO HYPERNEPHROMA.¹

BY FREDERICK TAYLOR, M.D. LOND., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL; PHYSICIAN TO THE
SEAMEN'S HOSPITAL, GREENWICH.

THE following case has many points of interest; these are—the nature of the primary tumour in the kidney, the occurrence of secondary growths, their pulsation, and the murmurs audible in them.

A sailor, aged 59, was admitted to the Seamen's Hospital, Greenwich, on Nov. 25th, 1907. He was found to have pulsating swellings of the right elbow, the right shoulder, and the right gluteal region, together with hæmaturia. The first occurrence of hæmaturia was in January, 1907, when it continued for three days. At first micturition was painful and clots of blood were passed, but with their passage the pain ceased. The urine continued to be bright red and the colour was evenly distributed. There was no pain shooting to the end of the penis and no pain in the loins or in the testes. The urine was then free from blood for two months. Hæmaturia again occurred; and every five or six weeks since then the patient had had similar attacks lasting two or three days. On Nov. 22nd the stream of urine was thought to be a little smaller, but no pain was felt. On the 24th, the day before admission, the patient was unable to pass urine until 1 P.M., when a few drops of blood-stained urine and clots were passed, and in the afternoon a large quantity of very dark urine. The swelling on the right buttock was first noticed 12 months ago, that on the elbow six months ago, while that on the shoulder had not been recognised, though the part was painful. Three weeks before the first occurrence of hæmaturia he had a fall on the right shoulder, elbow, and hip, and he had had frequent pains in these parts since that time. The pain in the right shoulder increased two days before admission.

The most obvious of the swellings was that involving the right elbow-joint; it was an elastic rounded swelling, and though affecting more the lower end of the humerus than the upper ends of the bones of the forearm it had very much the appearance of a moderately swollen joint. The movements, however, were not much limited, and both flexion and the radio-ulnar movements when carefully performed were not painful. The swelling was, however, tender to pressure, especially on its outer side, was soft and elastic, and pulsated distinctly. On auscultation a rather loud systolic bruit was heard. The right arm was wasted, but the muscle was capable of normal action. The tumour of the shoulder formed a rounded swelling of the acromial end of the clavicle and of the acromion itself, about 2 inches in diameter, and projecting above the normal level from $\frac{1}{2}$ to $\frac{3}{4}$ inch. It was soft, elastic, tender on pressure, and pulsating. A systolic murmur could be heard in it. The shoulder-joint was painful when moved.

The swelling of the right gluteal region was situated behind the trochanter, forming a flat elevation, projecting at its centre not more than 1 inch beyond the normal level of the skin. Its limits were difficult to define, but the pulsation associated with it could be traced upwards nearly to the iliac crest, backwards to the edge of the sacrum, and downwards to the level of the inner end of the trochanter. A systolic bruit was heard over this area. The right hip was painful on movement, and pressure behind the trochanter caused pain.

The course of the illness was uniformly downwards. The tumours gradually increased in size, and the patient became increasingly paler and weaker. The hæmaturia, however, was intermittent, and even for long periods absent. In January, 1908, he had pain in the left leg, but nothing could be detected to account for it. On March 1st the tumour of the shoulder extended, as estimated by the pulsation, from the spine of the scapula to just beneath the coracoid process, and measured 5 by 3½ inches. The tumour at the elbow was 5 inches in length and 10½ inches in circumference. The vertical extent of the gluteal tumour was as before, and antero-posteriorly it extended from the

anterior superior spine of the ilium to the tip of the coccyx. Blood was found at intervals in the urine, sufficient to colour it bright or deep red, and sometimes clots were passed. On these occasions strangury and pain at the end of the penis were present, but there was no pain in the loins. Beyond the presence of the blood-corpuscles and the corresponding albumin the examination of the urine was negative. In view of the presence of multiple growths in connexion with the bones, the urine was examined more than once for Bence Jones's protein. It was stated to be present on the first occasion, but subsequently it was never found, and I think the first observation must have been erroneous. The patient was pallid and wasted, looked much older than his age, and had the appearance of one suffering much pain. The lungs appeared to be normal. The heart's impulse was $\frac{1}{2}$ inch outside the nipple line; there was some accentuation of the second sound and a systolic murmur at the third left costal cartilage. Nothing was detected in the abdomen.

On June 16th the tumour of the elbow measured 11½ inches in circumference, that of the shoulder had increased to 6½ by 3½ inches, that of the right buttock to 10 by 9½ inches, and that of the left buttock to 3 by 4½ inches. The last two nearly met over the sacrum. Three weeks later a new pulsating area was discovered at the posterior extremity of the left iliac crest. On July 31st all the swellings were larger. The patient died on Sept. 18th, 1908.

The following account of the necropsy and the histological report are by Dr. Lucius Nicholls, then pathologist to the Seamen's Hospital, and now resident surgeon to the Victoria Hospital, St. Lucia, Windward Islands, W.I.:

Necropsy.—The body was that of an emaciated aged man. Four distinct hard swellings were visible upon the body surface; the first was a large oval swelling situated at the outer end of the clavicle; another was on the lower end of the humerus and involved the elbow-joint. The bone here was obviously fractured. The third and largest tumour was in the right gluteal region on the inner part of the iliac bone. The fourth was in the right lumbar region and appeared to involve the fourth and fifth lumbar vertebræ. These tumours were dissected out. The one on the outer end of the clavicle had caused fracture of that bone; it was 3 or 4 inches long and 2 inches broad, and it involved the upper border of the scapula. The growth on the lower end of the humerus was about the same size; it had also caused fracture of the bone and involved the upper ends of the radius and ulna. The gluteal tumour had involved the wing of the ilium and the adjacent half of the sacrum. This tumour was about 4 inches square. The sections of these tumours had the appearance of a lobulated structure, of a dark, mottled, bloody colour. This was due probably to extreme vascularity and hæmorrhages into the substance. Careful examination of the other skeletal structures revealed no further growths, and no bone broke on heavy manipulation.

The left kidney measured 5½ inches vertically. The upper third was occupied by a spherical tumour 2½ inches in diameter; it was lobulated and had a definite capsule. On section it presented hæmorrhagic areas. Throughout the rest of the kidney, except 1 inch at the lower pole, were scattered growths of the same kind, from the size of a pea to that of a filbert. The left suprarenal capsule contained a small separate tumour. The right kidney and suprarenal capsule were natural. The lungs were dry and silky, and contained numerous small nodules scattered through them, ranging from the size of a split pea to that of a small walnut. They could be easily shelled out. The cardiac valves were hard and sclerotic and the inner coat of the aorta was in an advanced stage of atheroma. The heart itself and the abdominal organs, other than the kidneys and suprarenal capsules, were normal and free from growths. The testes were normal.

Histological report.—The tumour is a so-called hypernephroma. In the present case the tumours are very degenerate, and much hæmorrhage has taken place into their substance. They have, however, the usual reticular appearance of hypernephromas, but the cells show badly and the nuclei are darkly stained. (The tumours of the kidney, humerus, scapula, and ilium, and histological sections, were shown at the meeting.)

¹ Read before the Section of Medicine of the Royal Society of Medicine.

There seems to be no doubt from the histological examination as well as from the character of the recurring growths that this case is one of those which have been called hypernephroma; but I am afraid that it contributes little to the discussion as to the origin of these tumours—that is, to the solution of the question whether they arise from suprarenal remains in the kidney or are only one form of carcinoma of the kidney.

Mr. Wilfred Trotter² says that a "true carcinoma of the kidney apart from hypernephroma is a very great rarity or possibly does not exist." Sir John Bland-Sutton says³ "the opinion is gaining ground that the majority of tumours classed as hypernephroma are carcinomatous, arising in the cells of the renal tubules, and I share in this opinion. The classification of malignant renal tumours is a difficult matter." In the French work on diseases of the kidney by Jeanselme, Weil, Chauffard and Laederich, the authors describe epithelioma with dark cells and epithelioma with clear cells. They admit that when the clear cells have a tubular arrangement they bear a clear resemblance to the cortical layers of the adrenals; and, indeed, that they are sometimes derived from adrenal remains; but that all clear-celled renal tumours have this origin they say is not true.

The case illustrates very well the metastasis to other organs, which is known to be a feature of hypernephroma. Though the lungs, liver, bowels, and lymph-glands are sometimes the seat of secondary tumours, it is especially the bones and muscles which have been observed to suffer; and these were the chief sufferers in the present case. Apart from the nodules in the lungs, these secondary tumours were four in number, involving in all cases the bones—namely, the right clavicle, the right humerus, the right ilium, and the fourth and fifth lumbar vertebrae.

Mr. Trotter in his paper makes it a point of practical importance that a hypernephroma often produces only one secondary growth. In a group of cases described by Dr. R. Hutchison, sarcomatous growths of the adrenals in children were accompanied by secondary growths in the skull only, but apparently these were not hypernephromas proper.

The fact that these growths pulsated requires some explanation. As a physician I have been haunted all my professional life by the warning that a pulsating abdominal or thoracic tumour may be, in occasional cases, not an aneurysm but a pulsating sarcoma. But I have rarely, if ever, been compensated for my fears by the discovery of such a growth. In my experience pulsating sarcomas are exceedingly rare. No mention is made of the probability of pulsation in these secondary tumours by Mr. Trotter. In Dr. Hutchison's group of cases no sarcoma of the bone appears to have pulsated.

Cancers of the liver, sarcomas and lympho-sarcomas of mediastinal glands, and other large masses of growths rarely pulsate. I saw, however, recently a renal growth which extended anteriorly in the upper part of the abdomen across the middle line, and this portion, lying as it did across or in front of the aorta, pulsated, and the pulsation appeared to be in the growth itself.

I presume pulsation must be dependent upon a high degree of vascularity, and the abundant hæmorrhage in these tumours found after death suggests that such a condition was here present.

The liver under special circumstances pulsates—that is, when by regurgitation through the tricuspid valve the right ventricle is able to impress the force of its contraction upon all the ramifications of the hepatic system of veins. In relation to the large hepatic vein when its current is reversed it is a highly vascular organ; but in relation to the small hepatic artery it is by no means highly vascular; and in health it does not pulsate sufficiently for clinical recognition. It is interesting to note that the liver, with its 60 oz. of weight, has an artery only half the size of the artery of the spleen with its weight of under ten ounces. And yet the spleen, with its relatively huge blood-supply and wide blood channels, is not clinically, even when enlarged, seen or felt to pulsate.

A similar interest attaches to the murmur which was heard over the pulsating growths. Blood is in health coursing rapidly and abundantly through muscles, the liver, and other structures, and yet there is no sound audible with ordinary means of investigation. What is the special condition of a vascular tumour which leads to the production of vibrations of sufficient amplitude to be audible?

Wimpole-street, W.

A CONSIDERATION OF SOME ELEMENTARY PRINCIPLES INVOLVED IN THE TREATMENT OF SOIL-CONTAMINATED WOUNDS.

By ALEXANDER G. R. FOULERTON, F.R.C.S. ENG.

A CERTAIN prevalence of tetanus and emphysematous gangrene amongst the wounded in Flanders and France has been inevitable under prevailing conditions of prolonged trench warfare on a highly cultivated terrain and during a season of heavy rain; and so it has become important to consider the best methods for preventing the special dangers incidental to the infection of wounds by the pathogenic anaerobic bacteria whose spores have habitat in the dust and soil. Recent discussion of this question has shown that there is some divergence of opinion as to the best methods for applying in the treatment of soil-contaminated wounds in particular the recognised Listerian principles which regulate the treatment of wounds in general. To some extent discussion has been academical; perhaps necessarily so, inasmuch as emphysematous gangrene has been something of a rarity in civil hospital practice since the general acceptance of and carrying into effect of Lister's teaching. So that it happens that few surgeons now can have had any but small experience in the treatment of this complication of wounds. Nor has attention been given usually in civil practice to any special methods for prophylaxis against the dangers peculiar to soil-contaminated wounds, except that occasionally a hopefully prophylactic but usually, under the conditions in which it has been given, probably useless dose of antitetanic serum has been injected subcutaneously. Otherwise, soil-contaminated wounds have been treated by the methods used in the treatment of "septic" wounds generally. There has not been question as to whether the pathology of soil-contaminated wounds is such that the best methods for their treatment are necessarily those which have been found to be the best for the treatment of other wounds which are liable to infection by, or which have already become infected by,

² THE LANCET, June 5th, 1909, p. 1582.

³ Tumours, p. 105.

the pyogenic cocci which are the cause of danger in a large majority of the "septic" wounds which the surgeon has to deal with in the routine of civil practice. The fact that the "hospital gangrene" of old times ceased to be a factor of possible importance after Listerian methods for the treatment of wounds had come into use is not really relevant to the matter under consideration. The type of emphysematous gangrene known as hospital gangrene, which once was seriously prevalent in hospital practice, was the result of an accidental secondary infection of wounds which were already under treatment. The disappearance of hospital gangrene as a serious complication of wounds in civil practice followed on the prevention of secondary infection from without of wounds under treatment by Listerian methods. Therefore there is not, so far, any evidence to suggest that the particular Listerian methods which have proved to be effective both for prevention of secondary infection of wounds by the common non-sporing pyogenic bacteria, and in the treatment of established infection by the same, are necessarily effective for the treatment of wounds which, either primarily or at any rate before coming under treatment, have been infected by anaerobic sporing species. Indeed, so different is the pathology of the two classes of wound infection that, whilst the fundamental principles of Lister's teaching must apply in either case, one might expect *a priori* that the effective methods for applying those principles in practice would differ with the general nature of the infection, whether by aerobic pyogenic bacteria or by anaerobic species.

As to the Biology and Pathogenic Activity of Strictly Anaerobic Bacteria.

The anaerobic bacteria which occur in the soil and which may cause emphysematous gangrene belong to several species. There is *Bacillus oedematis maligni*, the *Vibron septique* of Pasteur, which forms spores freely, and there are a group of species and strains which, with minor individual characteristics peculiar to each, conform generally with the type form described by Welch under the name of *B. aerogenes capsulatus* and with the nearly allied, or identical, *B. perfringens* of Veillon and Zuber and the *Gasbazzillus* of Fraenkel. *Bacillus aerogenes capsulatus* was described originally by Welch and Nuttall as a non-sporing species, but the formation of spores under certain conditions of artificial culture has been observed by bacteriologists in the United States and elsewhere. In fact, there has been some uncertainty of statement with regard to the sporing capabilities of this group of bacilli. Thus Slater¹ refers to eight strains of strictly anaerobic bacilli of the *B. welchii* type—isolated respectively from five cases of compound fracture caused by crushing, from one other case of lacerated wound without any fracture of bone, and from two cases of punctured wound of the eyeball—which did not show any tendency to spore formation. It is known, however, that anaerobic sporing bacilli are often apparently capricious in the manifestation of their sporing capabilities under conditions of artificial culture; and it is at least probable that all of this group of anaerobic facultative parasites have the power of assuming the spore form under natural conditions. Unless it were capable of assuming a resting and

resistant spore form when the conditions of environment became inimical to active growth, a strictly anaerobic facultative parasite would have little chance of long survival in a world in which strictly anaerobic external conditions are comparatively infrequent in nature, and then are possible only as the result of the activity of other bacteria which exercise on dead organic matter an aerobic fermentative action whereby all available free oxygen is used up.

The bacillary spore differs from the spores of higher species of fungi in that it represents strictly a resting and resistant form which is assumed when the environment becomes inimical to vegetation; the bacillary spore is never a means for multiplication. Amongst the higher mould fungi sporulation is essentially a method of multiplication, and the spores are often of but little higher resistant power than the vegetative forms. Amongst the yeast fungi the spore serves a double purpose, representing at the same time a resistant form and a means of multiplication. When conditions become unfavourable for growth, certain yeasts will produce, one, two, or more endogenous spores. Amongst bacillary species the spore is only a resistant form assumed for the protection of the individual cell in unfavourable circumstances: a single bacillus produces a single spore, and the single spore reproduces only a single bacillus when conditions favourable to active growth obtain again. Therefore, whilst there is not any doubt as to the spore-forming capabilities of *B. tetani*, and of *B. oedematis maligni* and *B. aerogenes capsulatus* amongst the bacteria causative of emphysematous gangrene, it may be assumed that the other strictly anaerobic bacilli which have been described in cases of emphysematous gangrene also have the power of passing into a resistant "spore" stage when exposed to the action of free oxygen.

The natural habitat of these bacilli is the intestinal tract of herbivorous animals, where strictly anaerobic conditions and a temperature favourable to their vegetation prevail. The bacilli are scattered over the ground with the excreta. After oxidation of the excreta by aerobic organisms and subsequent disintegration, the anaerobic bacilli become exposed to the action of atmospheric oxygen, pass again into the spore stage, and so remain until anaerobic conditions are re-established, either in the intestines of an animal or in a wound. Therefore the contamination of a wound with dust or surface soil will mean usually the introduction of spore forms. The introduction of active bacillary forms into a wound is probably rare; the ground air of loam contains, for a depth of many feet, sufficient oxygen to inhibit bacillary growth. On the other hand, when manure is stored in heaps the conditions are very favourable to the active saprophytic growth of anaerobic bacteria; the fermentative activity of co-existent facultative aerobic bacteria ensures at the same time the essential anaerobic conditions, and raises the temperature of the mass of manure to one favourable to the growth of, for instance, *B. tetani*. And so a man who wounds his foot with a fork when working manure may become infected by the active bacillary forms.

The loosely combined oxygen of the oxyhæmoglobin of circulating blood has, equally with free oxygen, an inhibitory action on the strictly anaerobic bacteria. Experiments carried out many years ago by Vincent and Roger showed that

¹ A group of cases in which the *B. welchii* or an allied organism was present. Reports from the Clinical and Research Laboratories, St. George's Hospital, London, 1910.

the injection subcutaneously, and with a minimum of traumatic disturbance, of sporing cultures of *B. tetani* did not cause tetanus when the specific toxins and any surviving bacillary forms had been destroyed by heat. Development of the spores was inhibited, and presumably they were destroyed by phagocytosis. Hence, under ordinary conditions, blood infection by bacilli of this class is impossible during life; bacilli which escape into the blood stream pass at once into the spore stage, and the inert spores disappear in course of time. But when a patient is dying slowly a general blood infection by anaerobic bacilli of the type of *B. aerogenes capsulatus* may occur before death happens. Thus the writer has seen the development of emphysematous patches on the front of the neck of a woman who was dying slowly with an anaerobic infection of the uterus after a criminal abortion had been induced by means of a dirty instrument. In another case, emphysematous patches developed in the subcutaneous tissue of the abdominal wall and of the buttock of a man who was dying very slowly after the perforation of a typhoid ulcer. In these cases dissemination of the bacillary forms becomes possible with an increasingly venous condition of the blood in the arterial circulation, resulting from gradual respiratory failure, and accompanied by a serious diminution of the oxyhæmoglobin content. And the like may happen in cases of emphysematous gangrene. It is uncertain as to how long it is possible for any inert spores which may have escaped into the blood to persist. Earlier workers had shown the harmlessness of the spores of *B. tetani* by themselves when introduced into the tissues under conditions such that immediate vegetation was inhibited. Later experiments recorded by Canfora² seem to show that the spores of this species, at any rate, may persist in the circulating blood and in certain tissues for a considerable length of time. Canfora injected guinea-pigs and rabbits subcutaneously with sporing cultures in which both toxins and bacillary forms had been destroyed by heat. Tetanus did not result in any case; but cultures of the bacillus were obtained from blood drawn off from the femoral vein as soon as 12 hours after the injection, and successful cultural tests demonstrated the presence of spores in the circulating blood as late as the thirteenth day afterwards. On the other hand, there is well-known experimental evidence that *B. aerogenes capsulatus* disappears from the circulating blood very rapidly.

The establishment of infection when a wound becomes contaminated with soil containing the spores of pathogenic anaerobic bacteria depends, then, upon a preliminary establishment of anaerobic conditions. The cavity of the wound, or some part of the wound, must become free from oxygen before the spores can become bacilli, and before bacilli can vegetate. The wounded tissues must be deprived of oxygenated blood before their invasion by the bacilli is possible. As far as the surface of the wall of the wound is concerned, the essential anaerobic conditions will often be provided at once. With injury by bullet or shell fragment, contusion of the tissues will be followed by temporary arrest of the capillary circulation of the surface exposed in the wound; and beneath the exposed surface there will be a zone of venous congestion. As a result of

the activity of facultative aerobic pyogenic bacteria the deeper parts of the cavity of the wound and any pockets in a lacerated wound will soon be deprived of any atmospheric oxygen. In this oxygen-free atmosphere the spores of anaerobic bacteria which have been introduced into the wound will develop; and the resulting bacilli, if of the type which cause emphysematous gangrene, will invade the adjoining tract of anaerobic tissue. In the case of a deep lacerated wound the anaerobic area of the cavity will increase automatically. Anaerobic bacteria, like all other forms of life, require oxygen for the purposes of metabolism. Unable to utilise free atmospheric oxygen they obtain what is necessary from the combined oxygen of dead organic matter; and, in the consequent decomposition of the organic matter, products with a low content of combined oxygen, or altogether free from oxygen, are formed. Amongst these products are quantities of gases, such as nitrogen, sulphuretted hydrogen, and the carburetted hydrogens, which will displace any remaining free oxygen from the wound cavity.

Up to this point, which marks what may be termed the establishment of infection, general considerations as to the pathology of the wound apply equally to all strictly anaerobic pathogenic bacteria. The further progress and results of infection must be considered with reference to the disease produced.

The Pathology of Tetanus.

Infection being established, it does not appear that the toxins of the bacillus of tetanus have any seriously injurious effect on the tissues immediately around the nidus of infection; nor do the bacilli invade neighbouring parts to any extent. Any local reaction following on the injection of a moderate dose of tetanus toxin usually subsides quickly, so that scarcely any trace of the inoculation may be found locally on the death of the animal, perhaps 24 hours afterwards. This absence of any sign of local tissue reaction sometimes characterises cases of chronic tetanus in man, when because of the insignificance of the original lesion and the absence of any local reaction the nidus of infection may be overlooked, so that the case is sometimes described as one of "idiopathic" tetanus. In tetanus, therefore, there is a simple toxæmia, the manifestation of which results from the special affinity of susceptible nerve substance for tetanus toxin. The clinical course of a case of tetanus appears to be determined mainly, and apart from the individual susceptibility of the patient, by the quantity of the initial dose of spores and the local facilities for the multiplication of the bacillary forms. With a heavy dose of infecting bacilli, or with their extensive multiplication in the wound, large quantities of toxin are carried by the circulation to the nerve centres, and also perhaps by direct conveyance along the nerve trunks supplying the wounded part. Whether carried directly to the motor ganglia by the nerve trunks, or whether abstracted by the nervous tissues from circulating blood, the symptoms of tetanus result when sufficient toxin has been accumulated in the nerve centres to disturb their functional activity. If the quantity of toxin is large, death occurs before any effective development of the autoprotective process is possible. If, on the other hand, the initial dose of spores is small, and the local conditions for their development are restricted, the rate of adsorption of toxin by the nerve centres is comparatively slow; so

² Ueber die Latenz der Tetanus-sporen im Tierschen Organismus, Centralblatt für Bakteriologie, Abt. 1, Orig., vol. xlv., p. 495, 1908.

that before sufficient toxin to impair seriously the normal functions of the nerve centres has been adsorbed the process of auto-immunisation against the toxin will be advanced, so that with or without the added effect of special treatment the process of immunisation may outstrip that of intoxication, and recovery occur.

The Pathology of Emphysematous Gangrene.

Whilst the bacillus of tetanus shows little tendency to invade neighbouring healthy tissues, and the symptoms of infection are essentially those of a toxæmia, the establishment of infection by one of the group of bacteria which cause emphysematous gangrene is followed by a progressive invasion of previously healthy tissues, after their exposure to the necrosing action of toxins formed by the bacilli. In detail, the course of a case of emphysematous gangrene is as follows. Anaerobic conditions having been established in some part of the cavity of the wound, the spores develop into bacilli which assume active growth. The tissue wall of the wound may be already, as regards its surface layer, in an anaerobic condition. But in any case an anaerobic condition will be rapidly induced by the necrosing action of the toxins formed. An invasion of the tissues by the bacilli then occurs. Once that the bacilli are established in the wall of the wound, the toxins cause a necrosis of fresh tissue in their immediate neighbourhood, and so prepare successive zones of anaerobic tissue which are quickly occupied by advancing bacillary growth. It is uncertain as to what extent the progressive necrosis is due to the direct action of specific toxins secreted by the bacilli or to the action of injurious by-products formed in the decomposition of tissues already invaded by the bacilli. For instance, amongst the by-products formed in the tissues is sulphuretted hydrogen, which itself destroys red blood cells by its action on the iron of the hæmoglobin. Nor is it known whether the general symptoms in emphysematous gangrene are caused chiefly by the absorption of specific bacillary toxins, or by decomposition products produced by the direct action of the bacilli on the tissues.

The Early Treatment of Soil-contaminated Wounds by Continuous Oxygenation.

The first objective in the treatment of soil-contaminated wounds is the avoidance of dangers incidental to the introduction of anaerobic bacteria or their spores into the wound. Common pyogenic bacteria will be present also; but the potential danger associated with these is a lesser danger. The sporing organisms may be dealt with by either of two methods, or by the two combined. Either the usual attempt to disinfect the wound by means of active germicides may be made, or the activity of the anaerobic species may be inhibited by the method of continuous oxygenation now described. Or, again, the method of oxygenation may be applied after the bacterial content of the wound has been reduced as much as may be by the other method. With regard to disinfection of the wound, only the most powerful germicides available are likely to be effective, under the conditions, against highly resistant sporing species infecting lacerated and soil-contaminated wounds. The treatment, if effective, will leave already damaged tissues with their vitality yet more impaired, and so will tend to increase the area of tissue reduced to an anaerobic state, and available

for the establishment of infection by bacilli produced by any spores which may have escaped the action of the disinfectant. If, on the other hand, the method of continuous oxygenation is brought in after attempted disinfection, the surgeon has a free choice as to the germicide to be used in the preliminary process. Subsequent oxygenation of the wound will prevent any danger arising from the production of an anaerobic condition of the tissues, which might be urged in objection against the use of an effective germicide such as pure phenol. Whilst satisfactory oxygenation of a wound by frequent irrigation with peroxide of hydrogen is practicable in civil practice, the method is obviously impossible under the conditions of field surgery. Therefore an investigation has been carried out as to the suitability to the purpose of certain substances which will yield a free supply of nascent oxygen when introduced, by insufflation, or otherwise, into a wound.

Whilst other compounds are available, the tests now referred to have been carried out with the peroxides of calcium and barium and with sodium perborate. Two samples of calcium peroxide were used, one with a stated yield of 9.75 per cent. of available oxygen, the other with a yield of 6.5 per cent. In determining as to relative suitability to the end in view, the following points have been investigated in connexion with the respective compounds: (1) As to their toxicity; (2) as to the quantity and rate of evolution of their yield of oxygen under different conditions; (3) as to the nature of the solid residue, if any, left after decomposition of the compound; and (4) as to the germicidal value of the evolved oxygen, as apart from its inhibitory action on anaerobic bacteria. Whilst the investigation is not as yet complete the results obtained so far justify recommendation of trial of the method in practice.

With regard to toxicity, it does not appear that the use of any of the three compounds could be followed by any injurious general effect. But the depressant effect of barium salts had to be considered. Decomposition of barium peroxide in watery solutions results, however, in the production of some barium hydrate and an insoluble residue of oxide which would not be absorbed by the blood. Suspensions in water of 1 gramme of the peroxide were injected into the peritoneum of the guinea-pig, and also subcutaneously, without any unfavourable result.

Next, experiments were carried out in order to ascertain the relative rapidity of evolution of oxygen under certain conditions from equal weights of the three compounds respectively. Equal quantities, by weight, of each were introduced into ordinary fermentation tubes, and the long arm of the tube was filled with 30 c.c. of either water, pus diluted with tap water, or a heavy suspension of washed red corpuscles in normal saline solution. The fermentation tubes were then kept at a temperature of 37° C. and the amount of oxygen collected in the long arm was read off from time to time. In the schedule of the results of experiments quoted below, the figures given represent, in cubic centimetres or in parts of a cubic centimetre, the volume of gas collected in a given time, and so represent the relative rapidity of evolution of oxygen. It is scarcely necessary to add that the figures do not show the total volume of oxygen given off from the given weights of the compounds, since a considerable proportion of the gas evolved is lost by escape from the open end of the tube.

The results of two experiments carried out with the purpose of determining the relative rapidity of the evolution of oxygen from the respective compounds when mixed with tap water are subjoined.

Experiment 1.

	60 min.	2 hrs.	24 hrs.	48 hrs.
Barium peroxide, 0.5 grm. in 30 c.c. of tap water	0.38	1.52	3.42	4.94
Sodium perborate, 0.5 grm. in 30 c.c. of tap water	0.38	1.52	7.22	11.78
Calcium peroxide (9.75% of available oxygen), 0.5 grm. in 30 c.c. of tap water	0.665	1.9	4.56	7.98

Experiment 2.

	60 min.	3 hrs.	24 hrs.
Sodium perborate, 0.5 grm. in 30 c.c. of tap water	about 0.2	1.52	11.4
Calcium peroxide (9.75% of available oxygen), 0.5 grm. in 30 c.c. of tap water	about 0.2	0.76	3.8
Calcium peroxide (6.5% of available oxygen), 0.5 grm. in 30 c.c. of tap water	about 0.2	0.76	3.8

With these and other similar experiments it was found that the results were not always exactly concordant quantitatively—a consequence of the somewhat rough method used for measuring the amount of gas evolved, and due partly to the unstable chemical condition of the compounds. But the results of the two sets of experiments given show fairly enough the relative rates of evolution of oxygen from each of the three compounds when mixed with water and kept at blood heat. In further experiment, the evolution of oxygen was estimated when the substances were mixed either with a heavy suspension of washed red corpuscles in normal saline solution or with a 10 per cent. dilution of streptococcic pus in tap water.

Experiment 3.

	90 min.	5 hrs.	24 hrs.
Barium peroxide, 0.5 grm. in 30 c.c. of red corpuscle emulsion	0.38	0.76	2.28
Sodium perborate, 0.5 grm. in 30 c.c. of red corpuscle emulsion	14.06	16.72	19.0
Calcium peroxide (9.75% of available oxygen), 0.5 grm. in 30 c.c. of red corpuscle emulsion	0.38	1.14	3.04

Experiment 4.

	60 min.	24 hrs.
Barium peroxide, 0.5 grm. in 30 c.c. of red corpuscle emulsion	0.76	2.5
Sodium perborate, 0.5 grm. in 30 c.c. of red corpuscle emulsion	9.5	15.0

Experiment 5.

	60 min.	3 hrs.	24 hrs.
Sodium perborate, 0.5 grm. in 30 c.c. of red corpuscle emulsion	12.92	13.68	17.86
Calcium peroxide (9.75%), 0.5 grm. in 30 c.c. of red corpuscle emulsion	0.38	1.14	2.66
Calcium peroxide (6.5%), 0.5 grm. in 30 c.c. of red corpuscle emulsion	0.38	0.95	3.42

In the next two experiments barium peroxide and sodium perborate were added respectively to 10 per cent. dilutions of two different specimens of streptococcic pus. For dilution of the pus in the experiment with barium a 0.6 per cent. solution of citric acid was used, and in the experiment with the sodium compound a 0.2 per cent. solution of boric acid. Mixtures of the compounds without the addition of pus were used for control purposes.

Experiment 6.

	2 hrs.	24 hrs.
Barium peroxide, 1 grm. in 30 c.c. of a 10% dilution of pus in citric acid solution	5.7	7.6
Barium peroxide, 1 grm. in 30 c.c. of citric acid solution	0.47	6.08

Experiment 7.

	30 min.	20 hrs.	96 hrs.
Sodium perborate, 1 grm. in 30 c.c. of a 10% dilution of pus in boric acid solution	20.54	24.34	24.35
Sodium perborate, 1 grm. in 30 c.c. of boric acid solution	8.74	15.96	17.1

From these experiments it will be seen that the evolution of oxygen from sodium perborate in the presence of water, and at a temperature of 37° C., is very much more rapid than from equal weights of either of the two other compounds. Sodium perborate and calcium peroxide being the more suitable for the oxygenation of wounds, it is of interest to compare them in view of the special requirement—the liberation continuously of effective quantities of oxygen. Experiments, of which Nos. 1 and 2 above are examples, have shown that in tap water the decomposition of the sodium and calcium compounds proceeds with a certain degree of regularity, whilst the ultimate yield of gas from the perborate is the greater. On the introduction of organic matter the evolution of oxygen is considerably accelerated, and especially so with the perborate. With this latter the evolution of gas is very rapid during the first three or four hours and then slows down, but appreciable quantities are still given off after 24 hours in some cases. The decomposition of the powdered perborate introduced into a wound would certainly be slower, however, than in these experiments, in which the perborate became dissolved fairly quickly in the considerable excess of water present.

Further experiments are in progress with the object of ascertaining whether it is possible to retard somewhat the decomposition of the perborate in the presence of organic matter, and so to produce a rather slower and more even supply of oxygen. And this, although an active initial production of oxygen, may be an important consideration in the treatment of heavily contaminated wounds. Other experiments are being carried out in order to ascertain whether by the addition of a small quantity of some such substance as citric acid it is possible to accelerate the evolution of oxygen from the calcium compound. But, in any case, the perborate used by itself will meet the essential requirements.

Another matter which had to be tested was the degree of alkalinity of the residue left after decomposition of the several compounds. The necessary titrations were carried out with mixtures which had been kept at blood heat during the period of experiment. Quantities of 50 c.c. of the respective mixtures were made up, and quantities of 10 c.c. were pipetted off for titration at the times stated. Phenolphthalein was used as the indicator. The pus emulsion tested in Experiments 9 and 10 was made up with pure streptococcic pus, but the proportional amount of pus used was not the same in each, and the pus used came from two different cases. The figures given show the percentage acidity, or alkalinity, in terms of hydrochloric acid and sodium hydrate respectively.

Experiment 8.

	60 min.	24 hrs.	48 hrs.
Barium peroxide, 1 grm. in 50 c.c. of tap water	0.02 NaOH	0.12 NaOH	0.096 NaOH
Calcium peroxide (available O = 9.75%), 1 grm. in 50 c.c. of tap water	0.008	0.04	0.096
Calcium peroxide (available O = 6.5%), 1 grm. in 50 c.c. of tap water	0.08	0.132	0.14
Sodium perborate, 1 grm. in 50 c.c. of tap water	0.103	0.72	0.412

Experiment 9.

	30 min.	24 hrs.
Barium peroxide, 1 grm. in 50 c.c. of tap water...	0.014 NaOH	0.102 NaOH
Sodium perborate, 1 grm. in 50 c.c. of tap water...	0.228 "	0.512 "
50 c.c. of pus emulsion	0.0145 HCl	0.0072 HCl
Barium peroxide, 1 grm. in 50 c.c. of pus emulsion	0.016 NaOH	0.104 NaOH
Sodium perborate, 1 grm. in 50 c.c. of pus emulsion	0.212 "	0.416 "
Barium peroxide, 1 grm. + 1 grm. citric acid in 50 c.c. of pus emulsion	0.6837 HCl	0.0181 HCl
Sodium peroxide, 1 grm. + 1 grm. citric acid in 50 c.c. of pus emulsion	0.6255 "	0.5055 "

Experiment 10.

	30 min.	22 hrs.
Sodium perborate, 2 grm. in 50 c.c. of tap water...	0.348 NaOH	0.796 NaOH
Sodium perborate, 2 grm. in 50 c.c. of pus emulsion	0.46 "	0.752 "
Sodium perborate, 2 grm. + 0.5 grm. boric acid in 50 c.c. of tap water	0.116 "	0.416 "
Sodium perborate, 2 grm. + 0.5 grm. boric acid in 50 c.c. of pus emulsion	0.72 "	0.92 "

As with the estimation of evolution of oxygen, the titration results were not always exactly concordant quantitatively, but it is evident that the degree of alkalinity produced in the decomposition of the perborate is considerably higher than with the two peroxides. But with this increased alkalinity there is an increased yield of oxygen, so that any favouring influence of alkalinity on bacterial growth is negated by the inhibitory effect of oxygen, as such, on the development of anaerobic species, and by a certain germicidal effect on other bacteria by reason of the nascent state of the gas. Also it appears from experiments which are being carried out at the time of writing that any excessive alkalinity can be avoided by the admixture of a small quantity of citric acid. The perborate dissolves slowly in pus and blood mixtures, and does not leave any insoluble residue. Both of the peroxides yield on decomposition a certain bulk of insoluble residue, which could, however, be removed readily from an open lacerated wound by syringing.

The Germicidal Value of Nascent Oxygen.

Since the special object in these investigations was to ascertain the practicability of inhibiting the activity of anaerobic organisms, it has not been thought necessary to investigate specially the known germicidal properties of nascent oxygen, beyond the carrying out of one or two tests for the purpose of confirming the activity of the gas as evolved from these compounds. Barium peroxide and sodium perborate were mixed in quantities of 0.5 grm. and 1 grm. with 20 c.c. of bacterial emulsions and incubated at a temperature of 37° C. The results were as follows:—

- S. pyogenes aureus.—Not affected by 25 minutes' exposure in 5 per cent. mixtures. Marked inhibition in peroxide 5 per cent. mixture after one hour's exposure and in 2.5 per cent. perborate mixture after two hours. Sterilisation in peroxide 2.5 per cent. mixture after two hours' exposure, and in perborate 5 per cent. mixture after one hour's exposure.
- B. coli communis.—Slight inhibition after 25 minutes' exposure in 5 per cent. peroxide mixture, sterilisation later. Sterilisation after 15 minutes' exposure in 5 per cent. perborate mixture.
- B. anthracis (sporing culture).—In one experiment, sterilisation after 24 hours' exposure in 5 per cent. perborate mixture. In a second experiment there was very little effect after 24 hours' exposure in 5 per cent. peroxide and perborate mixtures, but with each there was sterilisation within 48 hours.

The above experiments having been carried out with watery emulsions of the respective cultures, a few other experiments were carried out with

streptococcic pus and with an infusion of putrefying meat.

Mixtures of 10 parts of pus and 90 parts of normal saline solution were used, and sterilisation was effected in one experiment within 24 hours' exposure in a 5 per cent. perborate mixture; with another specimen of pus 22 hours' exposure in 5 per cent. peroxide and perborate mixtures failed to effect sterilisation, but the mixtures were sterile when examined 24 hours later. The addition of 5 grm. of either the peroxide or perborate to an infusion of putrefying meat resulted in sterilisation in within from 24 to 48 hours.

It would appear, then, that the germicidal activity of nascent oxygen evolved from sodium perborate is comparable, volume for volume, with the activity of the gas when given off from hydrogen peroxide. In either case the rapidity of the action of the gas on bacteria in a wound is affected materially by the presence of dead oxidisable organic matter which will divert the action of the gas in another direction.

The Application of Sodium Perborate to Wounds.

When there is opportunity for the early treatment of a recently soil-contaminated wound, and before the probability of any active vegetation of spores has to be considered, it appears that a thorough insufflation with sodium perborate, after any necessary preliminary cleansing, will effect all that is required in the way of inhibiting the activity of anaerobic bacteria; also the growth of other species which may be present will be checked by the action of nascent oxygen. In hospital practice, the insufflation could be repeated at intervals of less than 24 hours; but consideration of the experimental results suggests that if the perborate is applied freely there will be a continuous evolution of oxygen for the full period of 24 hours. Meanwhile, the dressing should be of the lightest possible description, and not more than is necessary to absorb discharges. If, on the other hand, the wound does not come under treatment until it may be reasonably supposed that there has been opportunity for the vegetation of anaerobic bacteria, and for establishment of infection of the wall of the wound, insufflation with the perborate should be preceded by thorough cleansing of the wound and swabbing out of the cavity with pure phenol, in the hope of destroying any anaerobic bacteria which already may have established themselves in the tissues. Objection has been raised to the use of phenol for the purpose, with the argument that the resultant destruction of tissue will provide an anaerobic area in which extension of infection will be favoured. But I do not think that under the conditions this argument is valid. The special bacteria concerned are those causing emphysematous gangrene; B. tetani does not tend to spread by invasion of tissue. If vegetating bacilli of the kind which cause emphysematous gangrene are already present in the wound cavity, it is merely a matter of time before they will have produced sufficient toxins to render the already injured wall of the wound sufficiently anaerobic to invite invasion. If the wall of the wound is already invaded, local extension of the infection will proceed automatically; and under those circumstances the only hope of arresting infection is by the use of a germicide which will reach the bacilli already established in the tissues. And, as a matter of fact, reference to the surgical literature of the days when hospital gangrene was of common occurrence shows that the means of treatment which were found most effective in arresting the spreading gangrene involved the free use of powerfully caustic agents, such

as nitric acid and arsenical preparations. However this may be, any possible objection to the use of phenol disappears if the activity of any bacillary forms remaining in the wound is inhibited by the presence of oxygen; and at the same time the destruction of any bacilli which have not invaded the wall of the wound to a depth beyond reach of the phenol is effected. In order to preserve the perborate in an anhydrous condition for field work it may be kept in an air-tight metallic receptacle containing a convenient quantity of the powder.

Vaccinotherapy and Serotherapy in Emphysematous Gangrene and Tetanus.

In spite of certain results which have been recently published by Weinberg³ it is difficult to conceive any scope of utility for either vaccine or serum treatment, either for the prevention of, or for the cure of, emphysematous gangrene. So far as one understands, it is in the essence of the disease that the spreading of the gangrene occurs by progressive invasion of tissues which have already been subjected to the necrosing action of the bacillary toxins, and in which the circulation has already ceased. For this reason, and quite apart from difficulty arising from uncertainty as to the species of bacillus against which prophylaxis is desirable, expectation of any advantage by the use of either a sensitised vaccine or an antibacterial serum would appear to be hopeless. Nor is there at present any prospect of obtaining an antitoxic serum which could be used with any reasonable hope of success. Such a serum would not in any way interfere with the activity of the bacilli in the infected area, whilst its effect on the general toxæmia would be, at the best, highly doubtful. The immediate cause of death in emphysematous gangrene is not known—as to whether it is the result usually of a septicæmia due to a secondary general infection by other bacteria, or whether it is usually the result of a toxæmia produced by the primary anaerobic infection. If the latter is the important issue, then we do not know to what extent the mischief is caused by specific toxins formed by the bacilli themselves, or to what extent decomposition products of the patient's own tissues are concerned.

The value, both prophylactic and curative, of the specific antitoxic serum in tetanus is recognised by all, but it is doubtful whether the serum is usually employed in the most effective way. When used for prophylactic purposes, the commonest practice has been to administer a single dose of serum as soon as the case has come under treatment. Antitetanic serum being purely antitoxic, has no effect on the activity of the specific bacillus, and does not in any way check the production of its toxin. It merely neutralises, according to its potency, some or all of the toxins circulating in the blood. If the antitoxin is introduced into the blood in sufficient concentration there will also be neutralisation of toxin already absorbed by, and accumulated in, the central nervous system. From the time when infection by *B. tetani* is established there is a continuing output of toxin, for the neutralisation of which a continuing administration of antitoxin is required so that a passive immunity is maintained. Therefore, if it is thought advisable to give antitetanic serum for purposes of prophylaxis, the dose should be repeated every second day for a period of 10 or 12 days.

³ Premiers Essais de Vaccinothérapie des Infections Gazeuses, Comptes Rendus de la Société de Biologie, vol. lxxvii., p. 543, 1914.

In view of the results of the work of Roux and Borel, 15 years ago, it is difficult to understand why intracerebral injection of antitoxic serum has not come into universal use in the treatment of developed tetanus, as the most effective method of neutralising the toxin accumulated in the central nervous system. The little operation necessary cannot, if performed with ordinary care, produce by itself any injurious result; and the advantage of introducing the antitoxin directly into the nerve tissue in which the toxin has been accumulated would appear to be obvious. It is at least doubtful whether injection of antitoxin into the cerebro-spinal sac has the result hoped for, when the operation is practised in the treatment of tetanus and other diseases in which the central nervous system is seriously involved. There is no reason to suppose that the effect of such injection is other than the effect of an injection given intravenously or subcutaneously. The cerebro-spinal sac probably represents a dilated efferent lymph track, and the flow of fluid will be from the sac into the blood, and not in the reverse direction—into the lymph spaces of the nerve substance.

University College, London, W.C.

A CASE OF PHENACETIN POISONING; RECOVERY.

By P. HAMILL, M.A., M.D. CANTAB., M.R.C.P. LOND.,
AND

T. G. M. HINE, M.A., M.D., B.C. CANTAB.

INSTANCES of phenacetin poisoning are sufficiently uncommon to justify the publication of the following case with a short commentary on the subject.

Mrs. —, aged 37, had been suffering for some time from chronic colitis, with a previous history of dysentery, for which she was being treated with a vaccine of a paratyphoid organism isolated from her stools. In order to diminish the reaction, which had been somewhat excessive with the ordinary vaccine, the organisms were sensitised after the manner of Besredka. Of this sensitised vaccine she received three injections, each containing 5,000,000 organisms, on Sept. 3rd, 7th, and 11th, 1914. The first and second injections produced no marked reaction except slight headache and local signs as of bruising. The administration of the third dose coincided with the onset of the catamenia, but the patient had not disclosed her condition to her medical attendant. She had been told that for headaches she might take one tablet containing 5 gr. of phenacetin every half hour until relieved, but not more than three consecutively. On Sept. 12th she was confined to bed with headache, which she did not report, and, contrary to instructions, took several 5 gr. tablets of the drug, but the exact number is unknown. (This fact was not disclosed until two days later.) Apparently she was well that evening, except for slight continued headache.

Early in the morning of the 13th diarrhoea set in, and continued until about 3 P.M. She was seen by one of us (T.G.H.) at 4 P.M., when her temperature was normal, pulse 80, and respiration natural. She was pale, had no nausea or vomiting, but said that her head had been swimming when she sat up, and there was some general malaise. Diarrhoea, as usual, had been her chief trouble, but this was ceasing. She said that she had recently (about 2 P.M.) taken two phenacetin tablets, the last in the bottle. She was advised to remain in bed, but no special steps seemed to be called for as the reaction to the vaccine appeared to be following its usual course. During the late afternoon the headache diminished. About 8.30 P.M. a telephone message was received to the effect that the patient looked rather blue, but she did not wish the doctor to come; she was advised to take a small quantity of brandy. At 10.30 P.M. an urgent call was received that she was very ill, purple in colour, and violently sick. She attributed the vomiting to the brandy she had taken.

She was seen ten minutes later. On examination she was very collapsed, of a deep dusky mauve colour, and wandering occasionally in her mind, but she recognised her medical attendant. She was retching violently and continually, and bringing up a little mucus. Her pulse was 120, very feeble; her respirations were shallow and uncountable because of the constant straining and restless movements. Strychnine, gr. 1/100, and digitalin, gr. 1/100, were administered hypodermically, hot bottles were applied, and she was persuaded to take some champagne. The condition was diagnosed as poisoning by some aniline compound, and phenacetin was suspected. The other of us (P.H.) was sent for, and arrived at 11.15 P.M. The patient was delirious, but had intervals of lucidity and periods of restlessness, alternating with others in which she was semi-comatose. She was still retching violently and continually. The vomit was scantier, but it was now blood-stained. The upper extremities were cold and the pulse was almost imperceptible. Strong coffee and small quantities of champagne were given, and oxygen was administered at frequent intervals in high concentration; under the influence of this the cyanosis changed its tint but did not disappear. Most of the fluid taken was vomited, though we think that a portion of the coffee was retained. Several half-pints of hot water were given by the mouth in order to wash out the stomach, but a tube was not used. The vomit gradually became colourless and less frequent. The patient's mental condition slowly improved, and about 12.30 A.M. (Sept. 14th) she smiled and laughed. The pulse was still well-nigh imperceptible; her colour oscillated between bright purple and deep blue, and at frequent intervals she sneezed. At 12.45 A.M. the patient was somnolent but restless; 1/50 gr. strychnine was given subcutaneously. Her respiration improved but was still feeble; the pulse-rate was 100 but much stronger. Her colour also lost some of the mauve tint, though her lips remained cyanosed. At 1 A.M. she was well enough to be left. Instructions were given that the vomit and urine should be preserved, but unfortunately this was not done.

At 9 A.M. the patient was still somewhat blue in the lips, and though feeling very weak expressed herself as much better, but was unable to sit up or get out of bed without feeling faint and unsteady. The temperature was 98.8° F., the pulse 96, and respiration normal. There was now no headache, but she still felt dizzy. There had been no vomiting since midnight, and no sweating. The bowels were opened once that morning, the stool being natural in character. Light food, such as meat essence and egg flip, was ordered, and sal-volatile if required, but nothing else for 24 hours. No rash was observed. Her further recovery was uneventful. A specimen of urine obtained during the evening of the 14th gave no reaction for paramido-phenol.

The patient later remembered little or nothing of her condition, was inclined to treat it very lightly, and said she suffered nothing at all. During the first hour and a half, however, her condition was most alarming, and we entertained grave doubts as to the issue. A month later her blood was 85 per cent. hæmoglobin, and red blood corpuscles 4,900,000, but she was pale and still had some dizziness and palpitation, which now have practically disappeared.

In this case certain data are unfortunately absent. The total quantity of phenacetin taken is not known, but could hardly be more than 60 gr., if so much, since she had taken during the preceding three weeks several doses from a bottle containing 25 5-gr. tablets; moreover, not more than 10 gr. were taken within the 24 hours preceding the onset of the symptoms. An accident by which the vomit and the urine were lost prevents our presenting definite proof that phenacetin was the toxic agent, but diligent inquiry failed to elicit that any other compound of this group had been taken. The outstanding features—namely, giddiness, deep cyanosis, vomiting, and collapse, with feeble respiration—have been described in the few cases of poisoning by this drug which have been reported. Sweating, however, was absent in this case, and we believe that early diarrhoea was the result of the vaccine rather than the drug, since it had been the prominent symptom in her reaction to all former

injections, and it ceased before the onset of the severe symptoms. A further point of interest lies in the long interval between the taking of the drug (the major part was taken on the 12th and the last dose about 2 P.M. on the 13th) and the onset of severe toxic symptoms late in the evening of the 13th. These events accord with our knowledge of the slow absorption and breakdown of phenacetin as compared with acetanilide and other bodies of this group.

It is worthy of comment that the specimen of urine obtained 24 hours after the onset of symptoms showed no evidence of breakdown products of phenacetin, whereas the urine of an albino rabbit (weighing 1600 grm.) passed 20 hours after it had received an intraperitoneal injection of 0.35 grm. (i.e., five times the maximum dose for man calculated per kilo of body weight) showed a well-marked reaction for paramido-phenol. The animal showed no further effects and took its food freely.

As regards the cause of the peculiar colour of the patient's lips and face—a deep dusky mauve—a question arises whether it was due to lack of oxygen resulting from circulatory failure or to some alteration of the blood pigment—e.g., the formation of methæmoglobin. We were unable at the time to collect samples of blood in order to investigate this matter, but it may be pointed out that so far as we could judge by artificial (electric) light the colour of the blood appeared to be more mauve than blue, and, furthermore, the inhalation of almost pure oxygen failed to restore the natural colour. Nevertheless, in the rabbit mentioned above no spectroscopic evidence of methæmoglobin could be found in specimens of blood taken at intervals after the injection, nor was any cyanosis of the ears or eyes visible by daylight.

We have traced records of two fatal cases in the literature of this subject. Fränkel¹ describes a case of a girl, aged 17, who died after taking 15 gr., and Krönig² reports the case of a boy of the same age who took five doses of 15 gr. in three weeks, the last of which proved fatal in three days. The symptoms of the latter case were similar to those of our own. Cases of severe poisoning with ultimate recovery after 100 gr., with a respiration rate of from two to three per minute, have also been recorded by Fränkel.³ Betts⁴ describes the case of a man who had taken three doses of 8 gr. each in six hours. His temperature fell below 95°F. Welsford⁵ reports a case in which 72 gr. were taken, with symptoms similar to our case; the duration of urgent symptoms did not exceed three hours.

Finally, it may be noted that our patient took the large doses of phenacetin on the second day of her catamenia. Brunton⁶ points out that many of the reported cases of collapse following the administration of substances of the antipyrin and phenacetin group have been in women during the menstrual period. He says:—

It would almost seem as if during this period there is such a change in the nutrition of a woman's organism that antipyrin and phenacetin seem to act more quickly upon the blood and to produce methæmoglobin, so it is well to be careful about the administration of these antipyretics when a woman is menstruating. . . . Now, it is just at this time that you are very likely to give them, because it is just at the menstrual period that women suffer more from headache than in the intervals.

TWO CASES OF TRAUMATIC HÆMOPERITONEUM.

BY C. HAMILTON WHITEFORD, M.R.C.S. ENG.,
L.R.C.P. LOND.

DISTENSION of the general peritoneal cavity by blood, as distinguished from localised blood effusions, is, apart from tubal pregnancy and extensive visceral injuries, uncommon. In neither of the following cases did the condition of the patient permit treatment of the bleeding area, but in neither case was there further hæmorrhage. In Case 1 the bleeding came from an infected wound of the liver. Such a condition, when the patient survives 17 days without further complications, would, in a sane person, probably result in recovery. As regards Case 2, there was no special difficulty in the operation and no reason to think that the peritoneal cavity had been entered through the uterine wall. The possibility that the bleeding might have originated in a pregnant tube was negated by the examination of the tubes at the second operation. The blood count exactly expressed the conditions found. The small leucocytosis in cases of hæmoperitoneum is probably due to infection of the effused blood by the staphylococcus albus, which was found by Dudgeon and Sargent¹ in 17 consecutive cases of ruptured tubal pregnancy. In perforation of the uterine wall, the result either of operation or of attempts at criminal abortion, excessive loss of blood is not common, such risk as exists being due to sepsis.

Incidentally Case 2 illustrates the advantages of performing even small operations in aseptic surroundings; the occurrence in this case of even a moderate degree of sepsis, such as is common in operations performed in bedrooms, would probably have proved fatal.

CASE 1.—A man, aged 22, stabbed himself in the left hypochondrium with a bayonet. The wound opened the peritoneal cavity and celiotomy was performed through the left rectus muscle. A handful of blood clot was removed from between the stomach and left lobe of the liver. Swabs passed into the pelvis returned dry. The source of the bleeding, which had ceased, was the left lobe of the liver, which was completely perforated 1½ inches above its lower border. No other viscus was injured. The abdominal incision was closed, and the bayonet track in the parietes packed with gauze soaked in tincture of iodine. Forty-eight hours later the lower abdomen became tense and tender and was drained suprapubically by a tube passed into the pelvis, many pints of blood and peritoneal fluid being evacuated. The gauze in the bayonet track was replaced by a tube. Both incisions suppurred freely. Food was taken well and the bowels acted regularly. The abdominal condition steadily improved, but the mania became more acute. Most of the known hypnotics were given in heroic doses but failed to secure sleep, and the patient died exhausted 17 days after the injury.

CASE 2.—The patient was a married woman, aged 39, who had had one child seven years ago but no other pregnancies, and in whom one and a half years ago menstruation began to last from four to seven weeks, without pain or inter-menstrual discharge. The loss was not sufficient to cause marked anaemia. The operation was performed in a private operating theatre. Per vaginam the uterus was found to be mobile and 3 inches in length, the cervix being unusually long. The only abnormality was a hard, submucous mass, embedded in the right side of the cervix and extending upwards in the uterine wall. This mass, which was not encapsuled, was dissected out, the right side of the cervix being divided and closed by sutures at the end of the

operation. The mass removed resembled in size and shape the two phalanges of an adult thumb, and was shown by the microscope to consist of avascular fibrous tissue with no signs of a capsule. Two hours after operation the patient rapidly became collapsed and almost pulseless. The collapse slowly passed off under stimulation and administration of saline solution per rectum. Fifty-six hours after operation there was definite peritonitis with distended immobile abdomen, dulness in the flanks, repeated vomiting, and complete intestinal paralysis, pulse 120, and acute pain.

A blood count by Dr. W. L. Pethybridge showed leucocytes 13,000 and red cells 50 per cent. below normal. A drainage-tube was inserted into the pelvis from above the pubes, evacuating over a quart of blood and peritoneal fluid. The Fallopian tubes, palpated through the suprapubic incision, were found free and not enlarged. The suprapubic drainage gave immediate and permanent relief to the pain. During the first two weeks broken-down blood clot drained freely per vaginam. Recovery ensued.

ROYAL SOCIETY OF MEDICINE.

SECTION OF MEDICINE.

Hypernephroma.—Latent Addison's Disease.

A MEETING of this section was held on Feb. 23rd, Dr. SAMUEL WEST, the President, being in the chair.

Dr. FREDERICK TAYLOR read a paper on a case of Multiple Pulsating Tumours Secondary to Hypernephroma. The paper appears in full at p. 483.

Dr. F. PARKES WEBER read a paper on a case of Bilateral Hypernephroma with Secondary Thrombosis of the Inferior Vena Cava and Terminal Uræmia. The case was that of a man, aged 49 years, whose suprarenal glands and kidneys on both sides of the body were infiltrated with a form of adrenal carcinoma or hypernephroma. There were likewise secondary nodules of the new growth in the liver and lungs. Venous thrombosis, commencing perhaps in the veins of the greatly diseased and enormously enlarged left kidney, involved both renal veins and both hepatic veins and the whole length of the vena cava, the clot extending continuously from the iliac veins below to the heart above. The upper end of the thrombus projected into and partially occluded the right auricle. The blood clot, examined microscopically close to the heart, was found to be secondarily infiltrated by the malignant tumour. The patient died from uræmia and almost complete anuria. It was remarkable that the patient lived so long as he did, and that his urine, in spite of the involvement of his kidneys, was passed in fair quantity and contained very little albumin till a few days before his death. The complete venous thrombosis of his best (the right) kidney doubtless brought about the final, almost complete, suppression of urine. As in other cases of thrombotic obstruction of the inferior vena cava, the enlargement of the superficial veins in front of the abdomen was a striking feature during life.¹ Dr. Weber said that in regard to the occurrence of thrombosis of the vena cava inferior, secondary to malignant disease of abdominal viscera, Dr. Herbert French had recently described and figured a very remarkable and instructive case in the Transactions of the Medical Society of London,² under the following heading: "Carcinoma of the Left Kidney, with continuous clot extending from the kidney along the left renal vein and up the inferior vena cava into the right auricle, and producing an intracardiac polypoid mass which led to tricuspid stenosis of the ball-and-socket type, the clot being infiltrated with carcinoma of the same type as that in the kidney itself." Dr. French's patient was a man, aged 45 years, whose chief symptoms were attacks of abdominal pain, with alternating diarrhoea and constipation, associated with pyrexia; the liver and spleen were enlarged, but there was no oedema of the legs. Dr. French stated that

¹ Cf. F. P. Weber: Ueber die Traumatiscche Thrombose der Vena Cava Inferior, Münchener Medicinische Wochenschrift, 1913, Band ix., p. 1434; also Transactions of the Life Assurance Medical Officers' Association, London, 1913, p. 254.

² French: Transactions of the Medical Society of London, 1912, vol. xxxv., p. 243.

various diagnoses were favoured during life, but the correct one was only arrived at in the post-mortem room. Likewise in the same connexion Mr. S. G. Shattock had referred him (Dr. Weber) to "a case of carcinoma of the testis in a young man, with metastatic deposits lying free in the heart and in the inferior vena cava," described by Dr. A. A. Kanthack and Mr. T. Strangeways-Pigg in the Transactions of the Pathological Society of London for 1897.³ The suprarenal glands, amongst the various organs of the body, exhibited a noteworthy peculiarity, to which his attention had been drawn by Mr. Shattock—namely, that they were fairly equally liable to tuberculosis and malignant disease. In both diseases the affection was not rarely bilateral. It was notorious that suprarenal tuberculosis was frequently bilateral, and indeed both adrenal glands might show extensive caseous changes without there being much evidence of tuberculosis in other organs of the body. Benign adenomata of the adrenal cortex were not rarely bilateral, as in a case which he had described in 1906.⁴ W. Roger Williams, in his book on "The Natural History of Cancer" (London, 1908, p. 301), referred to bilateral tumours of the adrenal glands in the following words: "In infants and adults bilateral forms of malignant adrenal tumours are occasionally seen. Rolleston and Marks, in 26 tabulated cases at all ages, met with two instances of this kind. A case which conclusively proves the bilateral origin of the disease had been recorded by Breton and Looten. The patient, a woman aged 57 years, having suffered for some time from symptoms of adrenal insufficiency, with a painful intra-abdominal tumour, died suddenly. At the necropsy each adrenal was enormously enlarged by small round-celled sarcomatous growth, which had secondarily invaded and caused enlargement of each corresponding kidney and the adjacent mesenteric glands. No other organs were involved. Similar cases have been reported by Fränkel, Woolley, Suchardt, and others. Adenomata of both adrenals have also been met with (Warthin)."

Dr. WEBER also read a paper on a case of Latent Addison's Disease revealed by necropsy following death from pneumonia. The patient, aged 35 years, was admitted to hospital in November, 1914, with the physical signs of pneumonia of the lower lobe of the right lung, and crepitation (without dullness) at the base of the left lung. His sputum had a "rusty" colour and contained capsulated diplococci. He was very obese and had "striae atrophicae" (analogous to the "linea albicantes" of women after pregnancy) over the abdomen, as often seen in exceedingly corpulent individuals. These he remembered to have been present for the last 12 or 13 years. His legs were oedematous and there were purple patches of cutaneous ecchymosis about his ankles and on his feet. He had arrived in London about ten days previously on his way home from Buenos Aires, where he had been ill for some time. In September, 1914, in Buenos Aires, he had had, according to the account, a transient attack of right hemiplegia. The doctor there had said that "his heart was very weak" and had advised his return to Europe. In London he had become acutely ill with orthopnoea and bloody expectoration. During the first four days of his illness in London his temperature was said to have been 102°-103° F., and later on 98°-100°. There was a history of malaria in North Argentina about two years ago. He was said to have had tuberculous pleurisy at about 18 years of age and jaundice and kidney disease during childhood. There was no history of alcoholism or venereal disease. It should be stated that on admission the patient had a peculiar yellowish tint noticeable in the skin of his face, though his conjunctivae were not jaundiced. During the first week under treatment in the hospital the patient's condition seemed not to get worse, though there were objective and subjective signs of great general debility. His temperature was nearly always between 98° and 99·5°; his respirations were at first 40-44 in the minute, but afterwards fell to 32-34; the pulse was at first 80-84, but later on mostly 100-108. The urine was of specific gravity 1012, averaging 1200-1800 c.c. in the 24 hours, and yielding a "thick cloud" of albumin; a few granular tube-casts and uric acid crystals were found in

it by microscopical examination. The signs of pneumonia at the lower lobe of the right lung persisted, but more crepitation than previously came to be heard, as if a certain amount of "resolution" were taking place. Some petechial or ecchymotic patches about the ankles ulcerated. The patient complained a good deal of abdominal pains, and said he had suffered from abdominal pains in Buenos Aires as well as on the ship during the voyage to England. In regard to treatment, strychnine, digalen, and a little alcohol were employed, and xeroform powder was used for the feet. The abdominal pains and discomfort were much relieved by hot hip-baths. Later on the temperature sometimes reached 100°, or slightly higher. The brachial systolic blood pressure was 155-170 mm.Hg. The superficial ulceration of the ecchymotic patches (superficial cutaneous gangrene) about the ankles and some superficial ulceration about the sacrum required much attention. The sputum was of the "prune juice" type, with a brownish tinge. Fifteen days after admission Dr. Weber tapped the right pleura and removed a little fluid, which was not quite clear and which by microscopical examination was found to contain a considerable number of pus cells. The specific gravity of this pleural effusion was 1010, and it "went solid" with albumin on boiling. Three days later he again tapped the right pleura and withdrew 1300 c.c. of a fluid somewhat turbid with pus cells. After another four days he tapped the right pleura for the third time and found the pleuritic effusion (about 1500 c.c. removed) distinctly purulent, foul-smelling, and swarming with cocci. There was therefore a definite empyema, and on the following day Dr. Zum Busch kindly operated under local anaesthesia, resecting a portion of a rib. The patient, however, grew gradually more feeble and died in a few days. In regard to the necropsy and microscopical examination Dr. Weber said that he was indebted to Dr. Hans Schmidt. The heart (weight 25 oz.) was much hypertrophied, especially the wall of the left ventricle; there was no valvular disease or ante-mortem thrombus. There were only slight atheromatous changes in the thoracic and abdominal aorta. A specimen of blood serum from the post-mortem heart's blood gave a definite negative Wassermann reaction for syphilis. The right lung (side of the empyema) was collapsed and there was an abscess or gangrenous patch in the lower lobe. In the left lung there was hypostatic congestion, and a microscopic section from the lower lobe (where crepitation had always been heard during life) showed the presence of chronic catarrhal changes. There was no ascites. The liver (weighing 106 oz.) was greatly enlarged, and had a fatty, pale yellow appearance. The upper surface was fixed by a few adhesions to the diaphragm. Microscopic examination showed an extreme degree of fatty change (fatty infiltration of the hepatic cells, doubtless associated with a degenerative condition of the cells themselves). The spleen (weight 6½ oz.) was rather soft and the capsule was attached by some perisplenic adhesions; a few pale patches observed under the capsule were shown by microscopic examination to be small infarcts. The pancreas appeared normal. The kidneys (weighing together only 8½ oz.) were rather small, and macroscopically and microscopically showed typical chronic interstitial nephritis. In regard to the other organs, the thyroid gland appeared normal; the testes were small for the patient's size, the weight of these organs (including epididymis) from both sides together being only three-quarters of an ounce. Both suprarenal glands were enlarged (the left one being about the size of a hen's egg, the right one as large as a goose's egg) and transformed into soft, pale, friable masses—evidently necrotic caseous material, including the whole of the medullary substance—covered only by a thin layer of living cortical substance. Further microscopical examination confirmed this. In the non-necrosed area were scattered foci of inflammatory small-celled infiltration; no tuberculous giant cell systems were found. It is noteworthy that the post-mortem examination showed no tuberculous changes, except in the suprarenal glands, and even in them the tuberculous nature of the caseous change was not definitely proved by microscopic examination. Dr. Weber remarked that in this case the old chronic interstitial nephritis with cardiac hypertrophy evidently counteracted to some extent the tendency towards very low blood pressure, characteristic of typical Addison's disease of the suprarenal glands. On the other hand, the patient's objective and subjective

³ Transactions of the Pathological Society of London, 1897, vol. xlviii., p. 139.

⁴ F. P. Weber: Symmetrical Adenomata of the Suprarenal Glands and Extreme Sclerosis of the Aorta, Transactions of the Pathological Society of London, 1906, vol. lviii., p. 338.

state of debility was characteristic, as well as doubtless the fragility of his skin and the imperfect general reaction of his organism towards infectious disease. He believed in this connexion that prolonged convalescence or a condition of unusual asthenia following ordinary attacks of infectious diseases might indicate the presence of latent disease of the suprarenal capsules (latent Addison's disease). In December, 1899, he saw a young man, aged 24 years, suffering from a pyrexial attack, which was regarded as influenza. The illness was accompanied by some pleurisy at the left base, and was followed by remarkable debility. There were several medical consultations about him, and he gradually apparently recovered. Later on, in 1901, he was attacked by malaria—apparently not a particularly severe attack—and was sent up to the hill station of Darjeeling. There his condition was one of great asthenia without fever, and he had syncopal attacks, in one of which he died. Some cutaneous pigmentation was observed in India, though none had been noted during the illness in England. A most careful post-mortem examination was made, and in a report sent over to a life assurance office in England it was stated that the suprarenal glands contained yellow, caseous material and calcareous plates and were matted together across the aorta. It seemed to him (Dr. Weber) that suprarenal disease (latent Addison's disease) was probably the true explanation of the asthenic condition connected with the previous illness in England.

SECTION OF ELECTRO-THERAPEUTICS.

Discussion on the Electrical Treatment of Wounds, Sinuses, Frost-bite, and Sprains, Considered more Particularly in Relation to the Present War.

A MEETING of this section was held on Feb. 19th, Dr. W. IRONSIDE BRUCE, the President, being in the chair.

Dr. KNOWSLEY SIBLEY introduced the discussion with a paper dealing with the general principles of ionic medication.

Dr. W. J. TURRELL read a paper dealing with the treatment of sprains and frost-bite, in which he advocated the use of the static form of electricity locally applied, and in certain instances diathermy. He gave instances where gangrene following severe frost-bite seemed imminent, yet with careful and persistent treatment this was averted, or if any local death did occur it was very much less than the appearances indicated as most likely to follow.

Dr. F. HOWARD HUMPHRIS related similar experiences.

Dr. CHARLES RUSS, in an important communication, said that it gave him pleasure to make a contribution to the study of the treatment of suppuration by active current. He believed that with a fuller recognition of the factors at work in suppuration the electric current would be found a very potent remedy. He first approached the subject at the bacteriological laboratory in 1907-09, and he believed there had lately been a realisation of the significance of bacteria in suppuration. On the one hand were the bacteria, associated with their toxins; of the poisonous nature of the latter members did not need to be reminded. Volume for volume, the strongest ordinary chemical antiseptics were poor in comparison. On the other side of the problem was the patient's resistance, and that consisted in changes in both volume and composition of the blood-supply, and in particular the emigration of polynuclear cells. Only when the latter had migrated to the site of a suppurating lesion were they known as pus cells. During the last three or four years he had been studying particularly the effects of electrical currents applied in a special way, and he hoped to show reason for his belief that there were factors directly antagonistic to the bad factors in suppuration which were assistants to the patient's resistance. The types of suppuration about which he would speak—and they were the types he had treated—were cases of ordinary chronic ulcer, such as varicose ulcer, acute septic wounds, usually due to trauma, and infected mucous membranes; in all those cases the factors he had mentioned were at work. In 1909 he had the privilege of reading before the Royal Society¹ a paper on some purely laboratory experiments and observations he had made on the movements of bacteria in fluids—i.e., during electrolysis. The type of organisms he studied were the disease-producing ones: staphylococcus pyogenes aureus, the commonest cause of sepsis, colon bacilli, typhoid bacilli, and other

leading groups. Taking the staphylococcus aureus as an example, one took a 24-hour pure culture of that on agar, put it into a tube with 2 per cent. sodium chloride, and emulsified it to keep the organisms alive. The current was then passed through by means of submerged electrodes. Certain facts then emerged. (Slides were here shown.) After a certain period it would be found that the staphylococcus had gone over until those microbes were completely aggregated at one of the electrodes; in the case under consideration it would be the anode. All the experimental work, which he did on the bench before approaching a patient, showed this emigration of bacteria, whether the bacilli worked with were dead or alive; it was due to the affinity between the moving ion and the bacterial envelope. Nearly all organisms in sodium chloride would go to the positive electrode. It came out in a very simple experiment which anyone could do on the bench. By passing a current of only three or four milliamperes the effect would be manifest in 20 minutes. He would not now enter into what were the variations in the different fluids. The second important fact was that if one withdrew a portion of the accretion after 20 minutes a large number of the bacteria would be found to be dead, showing that the procedure was lethal to bacteria. Two important facts came out when one was actually treating cases. The lethal effect could be applied against the bacteria in the focus of suppuration. He would instance the first case he treated as an illustration. It was a case of varicose ulcer, chosen because the lesion was easily visible and its varying size could be accurately measured; moreover, the technique could be well adapted to the leg. By the time the ulcer was chronic he found the bacteria were usually mixed; some of the ulcers were four inches square. His object was to draw the bacteria out of the granulations. He fitted a glass vessel over the ulcer and made it watertight with plasticine. He then filled it with a solution of sodium chloride and submerged an electrode, in that way establishing in the human being what he had been doing in the case of the test tube. Organisms left the granulations, as the current flowed from the indifferent electrode. Thus, over the lesion one brought a suitable column of fluid, and through that one arranged a circuit in such a direction that the bacteria would leave the lesion. He need not remind members of the perfect cellular contact which a conducting electrode made with all the irregularities of a limb. Sodium chloride was not looked upon as a powerful antiseptic, therefore the effect produced was not that of fluid antiseptics. He would like to mention an interesting control experiment which forcibly reminded him of the lethal effect. He wanted to prove whether the organisms were actually drawn out of the granulations, because, of course, no one could see them go. In the U-tube experiment there could be no doubt about the mass movement of the organisms; but on the limb one could not see it. He therefore, before treatment, put on clear saline, and stirred it up so as to get emulsion, and put $\frac{1}{4}$ c.c. of it on to an agar plate, and he intended to count the colonies. After passing the current he thought he would shake it up again to see if he had twice or thrice the number, the inference being that the multiplication was due to having drawn them out. He got a lot of colonies on the first plate—a thousand or so—while in the second he got nothing, showing that they were all dead. All the ulcers which he treated in that way were healed. His friend, Mr. C. R. C. Lyster, had treated a series of septic fingers, what were known as "casualty hands," the most severe half-dozen which the house surgeon could pick out for him. Pus was welling out from those terrible digits. The 2 per cent. sodium chloride was arranged over these lesions, and not one of the cases came to amputation, the result which often happened. Mr. Lyster, at that stage, was bolder even than he (the speaker) was, for he showed great adaptability in applying a column to the suppurating surface of the eye, corneal ulcers and conjunctivitis; nothing but the 2 per cent. saline fluid was used. The ulcers treated were pale, indolent, and of the washleather type, thoroughly anæmic, but at the end of 15 minutes from the current being passed the vessels were turgid and strongly congested, even to the point of oozing blood. That, of course, was in favour of the patient, for one had produced an effect equal to that of the Bier's bandage, the benefit of which was due to the enhanced blood-supply, the improved plasma flow,

¹ THE LANCET, July 3rd, 1909, p. 2.

and the increased phagocytosis. But the method he was describing could be used for parts of the body in which a bandage could not be applied. He had seen the good effect demonstrated in a distressing condition which he had studied more than anything else—namely, cystitis.² When he read his first paper a surgeon in the room said, "Why don't you draw bacteria out of a man's bladder who has got cystitis, for there is a suppurating mucous membrane which is accessible to a column of fluid?" A column of fluid could be put in, an electrode could be let down as a rubber catheter, and a belt carrying a metal core encircled the lower hip, and in that way one enabled the treatment to be applied to the whole suppurating and inflamed surface. He had taken old-standing cystitis cases of years' duration, whose case-books showed a monthly attendance at hospital, or perhaps fortnightly, and in which presumably all kinds of treatment had previously been applied. In all he got the same behaviour—namely, a decline in pus formation, and a great improvement in the symptoms, such as frequency of micturition, and an abatement of the symptoms which had been due to the chronic absorption of coli toxin. After an extensive experience in urine analysis, he knew that organisms in urine from cases of cystitis were seldom seen in phagocytosis; they were seldom seen inside the pus cells. But after treating cases electrically in this way he had some remarkable films showing polynuclear leucocytes literally stuffed with bacteria. Another point was that in chronic suppuration he had seen colon bacilli undergoing morphological change. After treating certain cystitis cases, keeping at the same time an eye on the urine, he found the bacilli becoming definitely longer and stringy, and changed in respect of their reaction to the standard Gram staining, showing an alteration in the chemistry of the protoplasm. When the bacilli attained this increased length they no longer had anything like the same virulence, and there was then no pus formation, or at all events very little. Pus disappeared from the urine after this treatment, and though he had watched cases for 12 months afterwards it had not reappeared, and the organisms remaining were still elongated. He was interested to see whether by passing a weak current through a tube of bacilli the bacilli could be elongated, and that happened, though not so long as in the cases treated. He had also done a considerable amount of work in the study of gonorrhœa in the male on the same principle. He desired, in conclusion, to project on to the screen a couple of charts from very chronic cases of cystitis. Although they showed only the frequency, the improvement in that respect was *pari passu* with the improvement in other respects, showing that the method truly overcame the causative agent at the back of the suppuration. The first case was at St. Peter's Hospital, and Mr. J. G. Pardoe handed the patient over to him in, he believed, an amused state of mind, for the man had been attending seven years, and had been getting out of bed to pass water five or six times nightly. The man was aged 56, a civil servant, dull, and therefore thoroughly reliable. He cross-examined the patient to get the clear facts. There were staphylococci, theropy masses, and the scalding and difficulty in micturition, as well as sleeplessness. The method described was applied to him, and the frequency came down, as the chart showed. One night it rose to five times again, but as it was Sunday he (the speaker) focused his attention on the prostate, with good results. The catheter came out stuffed with pus, evidently from the prostatic duct. The frequency came down, and the next night he got out only once. Treatment was finished on April 3rd, 1914, since when he had had no treatment. That, therefore, was a very good case. His urine was not yet free from staphylococci, but it was free from pus. The other case he wished to refer to was an acute one of six weeks' duration. He gave a course and then left him alone. It seemed to be going to relapse. When the frequency got to five times a night he decided to interfere and gave one administration for an hour, and he now had clear nights. At present he could not give more clinical material, but he hoped the remarks would be of service, because if electrical treatment were in future applied to suppuration he thought the method would be profoundly respected by surgeons.

Dr. T. J. BOKENHAM desired to say that his experience confirmed that of Dr. Turrell and Dr. Humphris in regard to

the electrical treatment of frost-bite and sprains. For the interference with local metabolism, such as trench frost-bite entailed, there was nothing to equal the effects of the static breeze discharge, but there must be a sufficient amount of discharge to cause benefit. He would say the same for some cases of indolent ulcer and obstinate sinuses, such as he had had to treat in the South African War cases, and at that date he was convinced that static electrical treatment was much to be desired. In the treatment of deep sinuses he had formed a good opinion of the value of ionisation, using sufficiently small currents, by means either of succinamide of mercury solution or with zinc electrodes amalgamated with mercury.

Dr. G. B. BATTEN desired to express his gratitude to Dr. Russ for his suggestive paper. That gentleman's experiments explained why Dr. Sibley got the good results which he detailed. Might it not be that when Dr. Sibley used zinc sulphate and zinc chloride he placed the limb practically in a positive bath, and immersed the rest of the body in a negative pole? Thus, while aiming at driving zinc ions into the tissues, he was also aggregating the deleterious microbes around one pole. Reasoning from that, Was it possible to get as good results with the substitution of a 2 per cent. salt solution for the fluid he used in the same way as Dr. Russ employed?

Mr. LISTER said the section was deeply indebted to Dr. Russ for making a great advance in knowledge concerning electrolysis. He had had the opportunity of treating a dozen or more cases on the lines Dr. Russ laid down, and he could speak with definite knowledge that quite as good, if not better, results could be achieved with simple salt solution so long as one employed a solution, not a pad. A solution admittedly could not be applied to all parts, but he had succeeded with legs, fingers, and eyes, and he exhibited the identical cups he used for those cases. Twenty years ago electrolysis was used with pads for driving in zinc, mercury, and copper, but the bacteriology of the matter had not been entered into until Dr. Russ did the work he had spoken of for the Royal Society. All present would feel deeply indebted to him for having come to the meeting to explain the process.

Dr. REGINALD MORTON wished to associate himself with the remarks of appreciation on the work which Dr. Russ had done; it was one of the most important communications which had been made to the section for a long time. It certainly explained many points concerning ionisation which were helpful. He hoped the record of Dr. Charles Russ's work was easily accessible, as he wished to study it closely. Dr. Sibley, in his remarks, had said that he used carbolic acid, lysol, and such substances; but it was new to him (Dr. Morton) that such substances would ionise at all. He would mention a practical point because last autumn he had an experience which caused him trouble. It was a case of ischio-rectal sinus, rather deep, which would not heal, although various methods of ionisation had been applied; the patient refused operation. What he finally succeeded with was an adaptation of an old method of getting through the chronic stricture of the urethra, using filiform bougies; and one of these found its way into the bladder. This method he applied to the sinus, using many zinc wires, and wherever he found a side track he placed a zinc wire into it, so that he got a wire in every side pocket. After that was accomplished healing occurred after a single application. Many sinuses following upon lacerated wounds were likely to be of the same nature, and it occurred to him that this hint might prove useful to some members. In view of the interesting facts related by Dr. Russ it was more than likely the case was cured not so much by driving the zinc ions in as by drawing the bacteria out and subjecting them directly to the lethal action of the electric current.

Dr. E. P. CUMBERBATCH said that in the treatment of sinuses his method was to pack the sinus with a zinc rod and connect it with the positive pole. In the cases he had been called upon to treat at St. Bartholomew's Hospital the method had been successful in some, but in others it had failed. When confronted with failure it was necessary to remember three things. First, the sinus might not be clear of foreign bodies. In one case a sinus was discharging a quantity of pus, and the orthodox zinc rod method failed. The case was sent back to the surgeon, who opened the sinus and found a piece of khaki in it of the size of the finger tip, which had not been seen in the radiograph. After the removal of that the sinus healed up at once. The second

² THE LANCET, Feb. 14th (p. 447), and Oct. 31st (p. 1040), 1914.

point was, was the sinus a straight one? If the sinus surfaces were not all touched by the rod, pus would still form. In one such case he had success by using a perforated metal rod, and very fine brass tubing as the positive electrode. He first washed out with water and saline, then zinc, and after passing the tube one got the disinfecting action of copper and zinc ions. Thirdly, one must make sure that the zinc used was a germicide. In many cases he found it was not, because the ulcer or sinus had refused to heal. As an alternative he had successfully used a solution of iodine in potassium iodide—1 per cent. iodide containing iodine dissolved to make it an additional 1 per cent. strength. It was not a case of simple solution of iodine and potassium iodide, but a chemical compound was formed, probably a tri-iodide. It could be proved that the newion entered when the electrode was connected with the negative pole. By placing a solution of this in contact with the skin the skin became discoloured a faint yellow, but by connecting the solution with the negative pole the skin became an intense orange or vermillion. Recently he had a case of ulcer on the knuckle which refused to heal with surgical treatment or with zinc ionisation, but at once yielded to iodine dissolved in potassium iodide. That being connected with the negative pole was one answer to the question raised by Dr. Batten. Another solution which had a germicidal action was sodium salicylate, and he had had a case which healed up with that after failure had been met with even from iodide. Another point he wished to mention in connexion with the treatment of sinuses and wounds was the use of X rays. Chronic suppurations and sinuses which had persisted for a long time and resisted other forms of treatment had yielded to X rays, and here again help would be derived by placing along the sinus a silver or tin rod. With regard to the treatment of frost-bite, it was first necessary to have an exact definition of "frost-bite," so that all who used the term would be referring to the same condition. He had had two cases of frost-bite in the feet of the anæsthetic type, and he had tried one foot of a patient with one method, and the other foot of the same man with another. He applied to one the rhythmic sinusoidal current to the worst side of one case, and to the other he applied the galvanic current which had been made to wax and wane. The foot treated with the sinusoidal current recovered much sooner than the other. In another bilateral case he treated both sides by diathermy, and the improvement in looks and in feeling began with the first application. In diathermy he started off by using moist pads soaked in salt solution, but later he placed pads on the skin which had had a little preliminary dabbing and the result was that there were fewer burns than by the other method. He had produced two bad burns by using a damp cloth pad in surgical diathermy, because the salt solution was converted into steam and this caused two large areas of necrosis; however, the case was moribund from malignant disease. Sprains in St. Bartholomew's students after football he found yielded to the simple galvanic current.

The PRESIDENT said he was sure members had derived a great deal of instruction from the discussion, and he could not close the meeting without saying how much he had been interested in Dr. Russ's remarks setting forth his own method of dealing with bacterial infection. He agreed with Dr. Morton that there was something entirely new in it which was likely to change the prevailing views concerning the electrical treatment of disease.

SECTION OF DERMATOLOGY.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Feb. 18th, Dr. J. J. PRINGLE, the President, being in the chair.

Dr. GEORGE PERNET and Dr. J. M. H. MACLEOD exhibited three interesting cases of Dermatitis Artefacta in women. In one of Dr. Pernet's two cases the left arm and shoulder had been involved for more than three years; in the other the front of the chest only was affected; in neither case was there any clue to the vulnerant employed. In Dr. MacLeod's case only the back of the right hand was affected, and its production had been preceded by the excision of a ganglion from the part.

Dr. J. H. SEQUEIRA showed a case of an Artificially Produced Eruption in an old soldier, who had presented a

similar condition on two previous occasions. The lesions somewhat simulated an eruption due to the halogens, but their primary bullous nature, lack of symmetry, and linear configuration all pointed definitely to their artificial production, a view which was unanimously shared by the section.—Mr. H. C. SAMUEL, Dr. GRAHAM LITTLE, Dr. PARKES WEBER, and Dr. PERNET discussed the psychology of persons who produced feigned eruptions, referring especially to the views of Freud on the subject.

Dr. LITTLE exhibited a case of Multiple Large Subcutaneous Tumours of 15 years' duration in a man, aged 49, which were asserted to have started from the seat of intramuscular injections of a phosphorus compound administered in Italy. The microscopic examination showed proliferative changes in the fatty tissue in addition to fibromatosis.—The case was discussed by the PRESIDENT, Dr. PERNET, and Dr. MACLEOD.

Dr. LITTLE also showed an old man with a typical Rodent Ulcer behind the left ear and Squamous Epitheliomata on the backs of both hands. He discussed the relationship between the two conditions, supporting the view that the term "rodent ulcer" merely connoted a clinical group of epithelioma.—The subject was fully discussed both from the clinical and pathological point of view by Dr. MACLEOD, Dr. SEQUEIRA, Dr. H. G. ADAMSON, and Mr. J. E. R. MACDONAGH.

Mr. MACDONAGH described and showed microscopical slides of a probably undescribed Protozoal Disease of the Skin which came on after an injury to the elbow in India.

Dr. S. E. DORE brought forward a case of Favus of the Glabrous Skin on the chin and neck of a young girl. The disease was probably of mouse origin, and this view was supported by the cultures exhibited.—Dr. ADAMSON thought the cultures resembled those of Sabouraud's trichophytic favus.—Dr. MACLEOD attributed the unusual character of the cultures to the medium on which they were grown.—Dr. DOUGLAS HEATH, Dr. LITTLE, and Dr. J. L. BUNCH also spoke.

Dr. KNOWSLEY SIBLEY showed a case of Morphœic Scleroderma, chiefly in the clavicular regions, with some patches of Alopecia Areata of the scalp in a middle-aged woman. He discussed the relation of the disease to the so-called "white-spot disease" and to generalised scleroderma.—Dr. BUNCH referred to the obvious differences between guttate scleroderma and atrophic lichen planus, and also to the views held in France as to its possible tuberculous nature.—The PRESIDENT referred to the relationship frequently existing between morphœa, alopecia areata, and disease of the thyroid gland. He pointed out that the patient had von Graefe's sign well marked. His experience was that such cases seldom or never eventuated in generalised scleroderma.—Dr. LITTLE and Dr. PERNET reported good results from the administration of thyroid extract.—Dr. WEBER, Dr. SEQUEIRA, Mr. SAMUEL, and Dr. A. EDDOWES also spoke.—Dr. SIBLEY, in replying, remarked that radiant heat had, in his hands, proved of value in such cases.

Dr. H. W. BARBER exhibited a case of Parakeratosis Variegata of about eight months' duration in a woman aged 38. The lesions were situated on the legs, where they closely resembled lichen planus, and on the face and neck, where their reticulated and riband-like atrophic band arrangement was characteristic.—Mr. SAMUEL referred to the presence of itching, which was generally considered to be unusual.—The diagnosis was confirmed by Dr. MACLEOD, the PRESIDENT, and Dr. ADAMSON, all of whom considered treatment unsatisfactory in these cases.

Dr. SEQUEIRA exhibited a case of Lichen Planus Hypertrophicus of 25 years' duration.—Dr. LITTLE advocated the use of carbon dioxide snow after erosion; Dr. ADAMSON advised the vigorous application of silver nitrate stick; Dr. HEATH reported good results from X rays supplemented by firm elastic pressure; Dr. DORE had had success with X rays; while Dr. DUDLEY CORBETT suggested ionisation followed by X rays.

Dr. CORBETT showed a very remarkable case of Nævus Linearis, which was confined to the right side except on the face.

ULSTER MEDICAL SOCIETY.—A meeting of this society was held in the anatomical department of the Queen's University of Belfast on Feb. 25th, Dr. J. S. Morrow, the President, being in the chair.—Mr. P. T. Crymble read a

paper on Instantaneous Skiagraphy as a means of Recording Normal and Abnormal Conditions of the Thorax and Abdomen.—Mr. Crymble and Dr. Foster Coates showed skiagrams of Phthisical Chests.—Mr. Crymble exhibited stereoscopic plates of the skull and of a dislocated shoulder-joint, and demonstrated apparatus for (a) instantaneous skiagraphy, (b) orthodiagraphy, and (c) localisation of foreign bodies.—Mr. A. Fullerton read a paper on the Mechanism of Enlarged Prostate, with some hints on the diagnosis and treatment, illustrated by lantern slides.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on Feb. 25th at the Stafford Rooms, Titchborne-street, Dr. Edgar G. Bulleid, the President, being in the chair.—Dr. E. G. Graham Little read a paper on Rodent Ulcer: its Nature and some Methods of Treating it. He pointed out that rodent ulcer had been described by Jacob in 1827 in terms which remained an admirable description of the disease, and he considered that much undesirable confusion had been produced in the modern conceptions of it which attempted to make of what was essentially a clinical group, and as such of much convenience, a microscopical entity, concerning the content of which there was no agreement. It was better to go back to the clear idea of Jacob and to regard rodent ulcer as a clinical term embracing all cases of ulceration of epitheliomatous tumours in which the cardinal symptoms of slowness of ulceration and absence of glandular invasion were present. He gave a clinical analysis of somewhat over a hundred cases of rodent ulcer occurring in his hospital and private practice. This series showed a very slight preponderance of males, which probably represented a usual experience, but in Bowlby's 66 cases there had been twice as many men as women, whereas in Dubreuilh's 166 cases there had been nearly twice as many women as men. As regards age, concerning which there was also very divergent experience, the largest number of cases had occurred between the ages of 40 and 60. He described results of treatment by several methods, and had personally come to prefer that of freezing with carbon dioxide, which he was satisfied compared quite favourably with any other method both as regards safety of application, convenience and rapidity of treatment, and permanence of removal. It was, of course, a truism to say that some types of rodent ulcer advanced in spite of all treatments, and he quoted several cases in which all the accepted methods had been tried in turn without avail. Dr. Little afterwards showed three cases of rodent ulcer which had been cured by means of the actual cautery, zinc ionisation, and carbon dioxide snow respectively. He also exhibited a case of probable rodent ulcer of the nodular variety.—Mr. Haldin Davis, who advocated excision whenever possible, Mr. V. Zachary Cope, and Dr. Frederick Langmead discussed the paper.

In the Section of Epidemiology and State Medicine of the Royal Society of Medicine to-day (Friday, March 5th), at 8.30 P.M., Dr. J. C. Ledingham will re-open the adjourned discussion on the Epidemiology of Cerebro-spinal Meningitis. This will relate mainly to the interpretation of the features of cerebro-spinal meningitis epidemics brought out at the opening meeting and to preventive measures. Members of other sections are invited to attend.

BRITISH HOSPITAL FOR MOTHERS AND BABIES.—The amalgamation of the British Lying-in Hospital from Endell-street with the Home for Mothers and Babies at Woolwich is now complete, the scheme having been sealed by the Charity Commissioners on Jan. 29th. The freehold of a site, just under three acres in extent, at Woolwich has been purchased, on which the new charity hopes to build, with as little delay as possible, a hospital for the reception both of lying-in patients and patients suffering from any kind of complications relating to maternity, either before or after child-birth. The committee has already £12,000 in hand for the purpose, but double this sum is needed before the project can be carried into full effect. The hospital is to be known as the British Hospital for Mothers and Babies, and will serve as a national training school for district midwives.

Reviews and Notices of Books.

Squire's Pocket Companion to the British Pharmacopœia.

By PETER WYATT SQUIRE. Second edition. London: J. and A. Churchill. 1915. Pp. 1040. Price 10s. 6d. net.

THE first edition of Squire's Pocket Companion appeared in 1904, when it was found that the older Companion was growing too bulky for convenience. Judicious condensation was therefore effected, the size of the page was reduced, smaller type and thinner paper being used. These changes facilitated the production of a volume which by size and weight might conceivably be termed a pocket companion. This book was specially designed for the medical profession, and contained information relating to such matters as commonly arise in the ordinary course of prescribing and dispensing. The general features of the book are already familiar to many of our readers. In alphabetical order of arrangement the monographs include a description of each drug with its usual method of preparation, to which are added notes on solubility, medicinal properties, prescribing notes, reference to incompatibles, a list of official and unofficial preparations, and an enumeration of antidotes for drugs possessing toxic properties. Comparison with the former edition is facilitated by special indication when the monograph relates to a new official substance; several of these monographs have been referred to, and the information afforded appears to be adequate.

Considerable space has been devoted to salvarsan, but although the chemical composition is clearly indicated by a formula and by a name consisting of 40 letters and three hyphens, nothing is said of the mode of preparation; we are told that "it occurs as a pale yellow amorphous powder." In the 13 following pages, however, nearly all that is important connected with salvarsan has been summarised, with thoroughly useful references to the literature of the subject. The methods of employment by intravenous, intramuscular, and subcutaneous injection are described in great detail, and the prescribing notes and special cautions are usefully appended. Prescribing notes of similar value are to be found in connexion with many other monographs, of which those relating to formaldehyde, iodine, menthol, and the pituitary gland call for mention.

The doses of the substances are given in both the imperial and metric systems, and there are tables showing the imperial weights and measures with the metric equivalents. In these the Pocket Companion strikes out a line of its own, which differs from the British Pharmacopœia; minims are rendered in terms of cubic centimetres, and the convenient, and officially recognised, mils, decimils, and centimils are ignored. In the body of the book, however, we frequently meet with a new and unauthorised contraction, "ml.," the meaning of which is unexplained in the text. Another departure from the British authority consists in the annexation from the German Pharmacopœia of the maximum single dose and the maximum daily dose of remedies possessing toxic properties.

The section dealing with antitoxins, serums, vaccines, and tuberculins has been very thoroughly revised to include the most recent information.

The Pocket Companion shows evidence of considerable judicious forethought in the selection of data likely to be of service to a wide class of readers. It supplies much practical information which is necessarily outside the scope of the British Pharmacopœia, and it does not encumber its pages with the many quantitative and qualitative tests which are of secondary importance to those accustomed to assume that all the drugs supplied to their order are bound to conform with the official standard of purity. We commend the book to all our readers for the valuable qualities which we have recorded.

A Text-book for Midwives.

By JOHN S. FAIRBAIRN, M.A., B.M., B.Ch. Oxon., F.R.C.P., F.R.C.S., Obstetric Physician with charge of Out-patients and in charge of Maternity Ward, St. Thomas's Hospital; Lecturer in Midwifery, St. Thomas's Hospital Medical School, &c. With 3 plates and 104 illustrations, five in colour. London: Henry Frowde, Hodder and Stoughton. 1914. Pp. 317. Price 10s. 6d.

THIS is a much more complete and ambitious work than the usual text-book intended for midwives. As the author says, it is open to the criticism of going beyond what is required of them and by them, but he points out that the more advanced modern school of practising midwife is possessed with an insatiable thirst for knowledge, and is rarely content with what has hitherto been given in books written solely for midwives. There is also another and a better reason which he puts forward for a comprehensive book—namely, that a more educated class is now proceeding to qualify as midwives, and for some time there has been discussion as to the advisability of raising the standard of training and examination. This book is the author's contribution towards meeting the legitimate aspirations of the midwife for a higher professional education. In a general introduction a summary of the simple facts of anatomy, physiology, and of bacterial infection is given which will serve both for study and also for reference. In this way Dr. Fairbairn attempts to supply that want of knowledge of the elementary principles of physiology which forms such a handicap to the teacher.

The author, of course, is always confronted with two difficulties: firstly, what to put in and what to leave out, and secondly, how to deal with those conditions in which the midwife is told by the rules of the Central Midwives Board to seek medical aid. As Dr. Fairbairn truly observes, from time to time a midwife will be called upon to treat some complication of labour without the assistance of a medical man, and unless she knows what plan of treatment she ought to adopt in these circumstances her patient may run a grave risk of losing her life. For this reason in many of the complications of labour a mode of treatment suitable to be undertaken by a midwife is described, although the author is careful at the same time to point out to the reader that the condition is one in which medical aid must be sought. The plan adopted of quoting in the text the various rules of the Central Midwives Board wherever they apply and discussing their rationale is a very good one, and will increase the utility of the book to the midwife and at the same time enable her to understand the reasons underlying the various rules under which she has to carry on her work. The teaching we need hardly say represents all that is best in the methods of the London school, and the whole is so clearly written as to be readily understood by any intelligent student. The

illustrations are numerous and good, there is an excellent glossary, and a very full index. We are sure the book will be welcomed and appreciated by the better class of midwife, and it should prove of the greatest assistance to them both in preparing for their examinations and as a trustworthy guide in their practice.

La Guerre en Bulgarie et en Turquie: Onze Mois de Campagne.

Par le Professeur OCTAVE LAURENT, of Brussels. With 302 illustrations. Paris: A. Maloine. 1914. Pp. 384. Price 6 francs.

Professor Laurent in this book not only describes the purely surgical experiences of the operations in the Balkans during 1912-13, but pays attention also to the condition of a country in a state of war and to the general questions affecting the treatment of wounded men under the circumstances. He speaks very highly of the Bulgarian soldiery and of their courage and endurance. It is pointed out that the Red Cross organisations gave their assistance entirely to the besieging forces at Adrianople, Scutari, Janina, and elsewhere, the besieged receiving absolutely no aid—that is to say, that except at Constantinople the European neutral powers in their succour to the wounded "conducted a veritable crusade against Turkey." The first part of the book is concerned with the general condition of Bulgaria, a study of its inhabitants, and of the medico-military organisation that existed. The second part deals in detail with the surgical experiences gained during the war. This part is very fully illustrated from photographs, and forms a very valuable contribution to military surgery. Dr. Laurent concludes that for every hundred men killed and wounded the proportions, according to the nature of the missile, would be: 12 killed and 15 to 20 wounded by shell, and 8 killed and 60 to 65 wounded by rifle shot—that is to say, that in the field shell causes most deaths, but three to five times (inadvertently stated "cinq fois") as many men are disabled by bullets as by shell. The relative severity of shot and shell wounds, and the proportion of each which become infective, have been carefully investigated. Primary infection occurred in 40 per cent. of shell wounds; and in 5 to 10 per cent. of bullet wounds. Erysipelas was rare. Dr. Laurent had 18 cases of tetanus, of which 5 recovered. Cholera, dysentery, enteric fever, and typhus fever prevailed at Chatalja, Adrianople, and in Macedonia. A large number of excellent illustrations give especial value to the strictly surgical portion of the work, which treats of the author's experiences in detail, and with the clearness of exposition and logical arrangement so characteristic of French scientific literature.

JOURNALS AND MAGAZINES.

Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B.; ALEX. MACALISTER, University of Cambridge; ARTHUR THOMSON, University of Oxford; ARTHUR KEITH, Royal College of Surgeons of England; and ARTHUR ROBINSON, University of Edinburgh. Vol. XLIX. Third Series, Vol. X., Part II. January, 1915. London: Charles Griffin and Co. Annual subscription 21s., post free; quarterly 6s.—The present issue is a rather bulky and a very well-illustrated one, but it does not strike the reviewer as one which adds very greatly to our sum of knowledge of the human body. Of the contributions relating to normal human anatomy the most important and most interesting is that of Mr. Geoffrey Jefferson dealing with the *Canalis Gastricus*. The author has collected and standardised information upon a subject to which several teachers

have for some time been in the habit of directing attention. Mr. Jefferson deserves the thanks of anatomists for carrying his anatomical knowledge into a clinical field and confirming it by careful X ray studies; he also deserves support in his appeal for a better understanding of the very obvious functional arrangements of the muscles of the stomach.—Mr. P. T. Crymble contributes a paper on Some Factors Influencing the Position of the Small Intestine. His results are derived from the study of 56 adult subjects, of which 6 were examined in serial frozen sections.—Mr. J. S. Fraser and Dr. J. K. Milne Dickie give a very well illustrated account of a Reconstruction Model of the Right Middle and Inner Ear, and Dr. John Cameron describes the Cranial Attachment of the Internal Lateral Ligament of the Lower Jaw. Neither of these papers demands any alteration of our general conception of the structures examined.—For the rest, the contributions deal with variations and anomalies.—Mr. C. P. G. Wakely describes a case of Duplication of the Ureters.—Mr. S. V. Telfer records a case of Abnormal Disposition of the Peritoneum, the anomaly being accompanied by an extensive hernia of the intestine into a peritoneal fossa situated on the right side of the abdomen beneath the transverse mesocolon.—Congenital Variation of the Pectoral Muscles is dealt with by Dr. Elbert Clark, who records a case of entire right-sided absence of pectoralis minor, accompanied by partial absence of the costosternal portion of pectoralis major of the same side.—Two papers, one by Mr. T. B. Johnston and the other by Dr. John Cameron, deal with the Morphology of Persistent Portions of the Left Superior Vena Cava.—Dr. R. J. Gladstone and Mr. W. Erichsen-Powell describe examples of, and discuss theories to account for, Fusion of the Atlas, and Manifestation of Occipital Vertebra.—Professor W. P. Gowland gives a note on a Diarthrodial Articulation between the Clavicle and the Coracoid, and Mr. J. R. D. Holtby records a case of Partial Lobulation of the Lung by Pressure of the Vena Azygos.—An obituary notice of Charles Barrett Lockwood is bound up in this issue.

Malaria e Malattie dei Paesi Caldi. Anno V., Fasc. V. and VI. September–December, 1914. Rome: Via Farini 62.—In this issue there are three original communications on Leishmaniasis, one by Professor G. Mariani on oriental sore, with special reference to its histology, which is illustrated by reproductions of the microscopic appearances. He finds a complete anatomical identity between the cutaneous forms of leishmaniasis of Asia and of the African and European shores of the Mediterranean and those of America known under the names of pian-bois, boschyaws, and bauru ulcer. Dr. G. Pavoni investigates the biological diagnosis of the disease, and finds that the deviation of the complement invariably gives positive results in external leishmaniasis, while in the internal form the results are for the most part negative. Furthermore, the deviation is complete and constant in cured cases, while in chronic cases tending towards recovery it is often positive. It is invariably negative in children who are not the subjects of the disease, so that a positive reaction is a certain sign of a diagnosis of leishmaniasis. The antigen used was a watery extract of spleen. In this relation it is interesting to note that in the third paper, by Dr. F. La Cava, the use of strong measures by caustics, excision, and cautery is deprecated. He states that the sore, if properly protected, heals spontaneously, and, moreover, affords an immunity against the general infection.—Other communications of interest are by Dr. P. Macri on Pruriginous Dermatitis caused by the Acarus of Dry Favus; by Dr. P. Vadala and Dr. F. Arezzi on Climatic Bubo in Messina; by Professor U. Gabbi on Ankylostomiasis; and by Professor G. Boeri on Amoeboid Dysentery.

The *Cornhill Magazine* for March includes a further instalment of Sir Arthur Conan Doyle's "Western Wanderings" and of Mrs. David G. Ritchie's "Two Sinners." "Behind the Mask" is a topical poem over the well-known initials "C. L. G.," from which the last verse may well be quoted:—

He always kept a smiling face,
He never groused when he was soaking;
And in the very tightest place
Became most prodigal of joking.
He jested in the jaws of Death;
He kept at bay that grim marauder;
And with his very latest breath
Was imitating Harry Lauder.

"An Editor" writes of "A Newspaper in Time of War," and

with much psychological acuteness declares his approval of the Censorship. "It is, of course," he says, "very unintelligent—that is the source of its strength. The collective intelligence of a body of men, individually clever, is always very low, a psychological fact to which is due the success of Parliamentary Government in this country. As a race we would never endure to be governed by a man of genius—except maybe temporarily in time of supreme crisis. We tried the experiment once with Cromwell and replaced him by Charles II. and his corrupt ministers—a typically British sequence of choice. When this war is over we shall politely but very firmly shove Lord Kitchener out of the War Office and replace him by an Arnold-Forster. And we shall be right! The profoundest thing in our deep political instinct is its distrust of genius. We use it—occasionally—but we always hate it and distrust it. And we are right. Genius may win an empire, but only honest stupidity can hold one." In every department where science holds sway this is exactly the British spirit which it is hoped that the war may abolish.

THE ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD FOR 1913-14.

(Concluded from p. 382.)

II.

IN the section following that on infant life protection the medical officer deals with the question of administrative control of infectious disease, the local incidence of which was shown in March last, when the third annual statement respecting notifiable disease was issued by the Local Government Board.¹

In a comprehensive table relating to the county of London and to England and Wales as a whole the number is given of cases reported in each of the years 1911-13, together with the corresponding case rates for the several diseases.

Scarlet Fever.

The history of scarlet fever incidence in 1913 is interesting, inasmuch as it shows that although for the most part the cases exhibited the mild type prevalent in recent years, the mildness was by no means uniform everywhere. The records of 1913 confirm the experience of previous years, when in some northern areas of England scarlet fever exhibited exceptionally high fatality. In a recent epidemic in the Sunderland rural district the disease is reported to have shown a marked septic tendency, characterised by unusually severe inflammation of the throat, with enlargement of the cervical glands and rhinitis, thus indicating a reversion to the severer type prevalent in former years.

Diphtheria.

Diphtheria mortality showed in 1913 a fall of 60 per cent. from the rate of 1901. Nevertheless, the behaviour of the disease during the year was in some respects peculiar. As in the year 1912, the highest London attack-rates were reported in Woolwich and in Greenwich, the lowest in Kensington. Among other administrative counties the attacks were most frequent in Flintshire and least so in West Suffolk. In the course of the year several local prevalences of diphtheria were investigated by the Board's medical staff. Outbursts of the disease occurred in Sherborne, Dorchester, and Rochford, in all of which infection was spread mainly by personal contact. Instructive particulars are given of the investigation of an outbreak of diphtheria in South London attributable to milk infection.² In this case the difficulty of tracing the source of infection was increased by the circumstance that the milk was derived from numerous widely distributed farms in the counties of Surrey and Sussex as well as from the dairyman's own cows in London. Credit is due to the health officers of the respective districts for their prompt recognition of the cause of the outbreak, as well as for their adroitness in accomplishing its suppression. The efficiency of pasteurisation when properly employed in rendering harmless a milk contaminated by an easily killed organism like the diphtheria bacillus was abundantly proved by this outbreak. Dr. J. Priestley, the medical officer of health of Lambeth, at once resorted to this prophylactic, which apparently cut short the epidemic. Inquiry from all other sources having proved fruitless, important positive information was elicited by

¹ THE LANCET, April 4th, 1914, p. 993.

² THE LANCET, June 6th, 1914, p. 1623.

Dr. S. Child, medical officer of health for West Sussex, who detected sores on the udders and teats of some cows at a milk farm at Horsham; added to which the hands of three out of the four milkers at the farm were found similarly affected. From the sores on the hands of two of the milkers virulent diphtheria bacilli were isolated, but the swabs taken from the throats gave negative results. Consideration of all the circumstances suggests the probability that the sores on the milkers' hands were caused in the process of milking by contact with the sores on the teats of the cows. On this hypothesis, the explanation of the outbreak appears to be that sores on the cows' teats became infected with diphtheria from some unknown source, and that the infectivity of the milk for its human consumers was increased by accidental infection of the milkers' hands from the diseased teats. The extreme virulence of the infective organism is proved by the fact that in the case of one of the milkers affected the condition of the ulcerated finger was such as to require amputation. The operation having been performed, the amputated finger was sent to the Clinical Research Association with the result that a virulent diphtheria bacillus was isolated, which on inoculation into a guinea-pig caused the death of the animal in 48 hours. The foregoing investigation is instructive as showing that active diphtheria bacilli can survive in other situations besides the human throat.

Typhus Fever.

There has been no serious occurrence of this disease in England during the year under notice, the total number of fatal attacks in 1913 being only 12. In several instances typhus fever was notified in error; and of the 18 cases certified as from this disease 7 have subsequently been held to have been wrongly diagnosed. Occasionally a case of true typhus is mistaken for one of enteric fever, and is notified under the latter name. For these reasons all notified cases of enteric fever where the symptoms are anomalous are deserving of the closest scrutiny. Of the 11 notified cases (probably or certainly typhus) one occurred in Bermondsey, another in Shoreditch, and two in Stepney. Four cases were notified in Liverpool, one in Wigan, and one in the urban district of Cowes. In certain parts of Eastern Europe typhus fever is endemic, and foreign returns indicate its prevalence in parts of Austria, especially in Galicia, and to some extent in Russia. It has been described as the pestilence which commonly accompanies or follows war. Accordingly, it is desirable, at the present time, that medical officers of health should be constantly on the watch for its appearance.

Enteric Fever.

No interruption is recorded in the steady fall of enteric fever fatality which England has experienced for many past years. Compared with 1901 the death-rate of 1913 has declined by 70 per cent. Throughout that year the incidence of attack was on the same low scale as that obtaining in 1912. In England and Wales the sickness-rate was 22 per 100,000 living, as against 38 and 23 respectively in the two preceding years. As usual, the rates varied enormously, ranging among administrative counties from 4 per 100,000 in Hereford and in Montgomery to 47 in Northumberland and 50 in Lancashire. An outbreak of enteric fever occurred at Kenilworth, in which circumstances pointed to the public water-supply as the probable cause of mischief.³ On investigation it became clear that an "adit," from which this supply was derived, must have received water from a brook fouled by the discharge from a storm overflow of a section of the Kenilworth sewers. Towards the end of the year 41 persons were attacked with enteric fever, 26 of whom fell ill within a week. Some days previously there occurred in Kenilworth a general prevalence of gastro-enteritis, which was probably, though not certainly, connected with the sewage pollution of drinking water. The foregoing occurrences at Kenilworth furnish yet another illustration of the necessity of keeping under constant observation the purity of public water-supplies. Long immunity from water-borne infection may induce false impressions of security unless local possibilities of contamination are sought for and remedied. Special importance now attaches to this matter, in view of the possibility of military operations, which, besides increasing the demand upon local water-supplies, might expose the sources of those supplies to danger of pollution. As in previous years,

occasional outbreaks of enteric fever have been officially attributed to the eating of shell-fish contaminated by sewage. In reporting upon a recent epidemic of this disease in Portsmouth, involving the illness of 140 persons, the medical officer of health expressed the belief that most of the enteric fever in that town is due to eating shell-fish which has been contaminated with sewage. Although attention has frequently been drawn to this danger in his reports the warnings have fallen on deaf ears. The shell-fish are regularly collected from obviously polluted places, at times within 100 yards of the sewage outfall. The health officer further points out that when once the shell-fish are gathered there is nothing to indicate whether or not they come from a polluted source so long as they appear fresh, although they may be loaded with typhoid bacilli. Dr. J. Niven's report for Manchester contains particulars of an investigation by Dr. B. M. Cunningham on the relation of mussels to enteric fever. The inquiry related to 108 cases occurring in that city. In every case uncooked mussels had been eaten within three weeks of the onset of fever. One-third of the patients were beer-drinkers to excess, among whom the eating of shell-fish is a well-known habit; this commodity being habitually purveyed outside the public houses, or even in the bars. The facts elicited supported the conclusion that the mussels were probably the cause of enteric fever.

Tuberculosis.

The more accurate knowledge of the behaviour of tuberculosis gained under recent provisions for its notification has considerably increased the efficiency of measures for its administrative control. Incidentally a large addition is thus caused to the work of the Board's medical department, corresponding to which is the fuller treatment of the subject noticeable in Dr. Newsholme's recent reports. As far as can be judged from another year's experience the notification of tuberculosis has been accompanied by less inconvenience and friction than was originally anticipated. In some instances the public health possibilities of notification have not been realised, in consequence whereof only imperfect action has resulted. Nevertheless, it is believed that with the fuller development of tuberculosis schemes the public health advantages dependent on notification will be more uniformly secured. One of the principal difficulties hitherto encountered has been that in certain instances dismissal from service has followed the knowledge that an employee was suffering from tuberculosis. In regard to domestic servants, for example, the advice is given that the first interview after notification should take place at the office of the medical officer of health, rather than at the employer's house. Again, in the case of a school teacher with open tuberculosis, the aim should be to adopt a course which, besides minimising risk of infection, may conduce to the personal interest of the sufferer. In both the foregoing circumstances this can best be effected by consultation with the patient's own doctor. In the event of the school teacher becoming unfit for the discharge of his duties, the anticipation of a pension, due at a later stage, in such cases may diminish the hardship involved.

The general decline in the mortality from tuberculosis observed in recent previous years has continued in the year under review. In the present report details are given of the local distribution of the fatal cases and their incidence on age and sex; but for these statistics reference is necessary to the original, as they do not admit of summary in a brief notice like the present.

It frequently happens that the first notified case is not the first clinical case of tuberculosis in a family; and from the standpoint of prevention the detection of such early cases is important. Examination of contacts sometimes discovers patients in an earlier stage of disease than the notified patient. The probability of effecting a cure is very much greater where the disease has been recognised before bacilli commence to be discharged in the sputum. Consequently the success of any scheme for dealing with tuberculosis must depend on accuracy of diagnosis of early cases. At the time of notification a large proportion of cases of pulmonary tuberculosis are found to be in an advanced stage. Late notification is mainly due to the patient's neglect to obtain medical advice; but in not a few cases there appears to have been medical delay in recognising the disease. In these cases examination of sputum would have ensured earlier and more satisfactory treatment.

THE LANCET.

LONDON: SATURDAY, MARCH 6, 1915.

The National Support of Science.

It is difficult to believe that when an intelligent nation, or at any rate a highly civilised nation, is confronted with a critical economic problem it will fail to draw on its best energies in arriving at the solution. Nor is it thinkable that the position of a political party or of commercial persons can count when the fate of a great national industry is at stake. Yet it is the fact that the vast British textile trades will be seriously inconvenienced unless substantial aid from financial, scientific, and political directions soon occurs. The great Government departments have done splendidly in mobilising military forces; they must lose no time in mobilising with like success the chemical activities of the country, or there may spring into being an army of unemployed of not less than a million and a half of able-bodied operatives. That, at all events, is the position into which the British textile trades are drifting unless our national output of dye wares can be increased to meet the deficiency of supply occasioned by the cutting off of German imports. This huge industry depends for its commercial success upon the use of dye-stuffs which in value amount to £2,000,000 per annum, and only 10 per cent. of this is produced in this country. Disaster not only to this industry but to many businesses with which it is intimately bound up is imminent if the supply of dye-stuffs cannot be obtained on the same scale as obtained before the outbreak of the war. The medical significance of the situation is apparently remote, but only partially so. First, anything that has to do with the production of dye-stuffs bears in the closest way upon the manufacture of synthetic remedies; while, secondly, and more generally, all medical men are interested in any measures taken by the State for the support of scientific work. If we can annex from Germany the spirit that made the German Governments turn to the best scientific advisers in all difficulties, we can afford to neglect territorial acquisition as much as any hardened pacifist, while rejoicing in what we gain.

If this country really sympathises with the scientific spirit, to return to the position of the textile trade which we have used as an example, there would be no disagreement between the work done in the laboratory and that done in the factory. It is said very truly that research cannot be hurried, but that is all the more reason why the services of the practical scientist should be rapidly secured. In some directions, no doubt, research will

be required, but we believe that the really profitable study will be the intelligent application of established results of scientific work to the factory. The men wanted mainly will be those who can take an experiment from the test-tube to the great plant of the chemical factory and successfully produce there in tons what they can obtain in grammes in the laboratory. That achievement sums up what the Germans have done, backed, of course, by powerful Government financial support in their great chemical interests, which produce dyes, synthetics, and a host of other chemically refined products. We are well aware that the main successes of German chemical trade have taken time to achieve, but it is equally true that the principles of method which have led to these successes are perfectly well known to British chemists. What our rulers have failed to appreciate appears to be the fundamental importance of lay recognition of scientific claims, so that the expert and the merchant can coöperate. Success, commercially speaking, can only be secured by the collaboration of business acumen and scientific ability with technological knowledge. The man of business, important though his rôle is, knows as a rule little of the workings of the methods he finances; the scientific man invariably is a stranger to business methods, while his discovery may remain only a laboratory fact until the technologist is consulted. With the advent of the engineer, who can foresee difficulties on the large scale, who can overcome them by his practical knowledge of the adaptation of test-tube experiments to the demands of the vat and filter press, and who is familiar with operations conducted in commercial bulk, true collaboration is established. It is rare that such a collaboration exists in the industries of this country, and that is why in some directions we do not possess the strength and position of the German industrial leaders, who perceived long ago that a well-paid scientific and technological staff was indispensable to the success of their works.

Unless this sort of collaboration is established in this country it will be difficult to relieve the grave shortage of those supplies of dye-stuffs which are essential to the British fabric trades. Though we possess many highly trained men, chemists and technologists, their services are seldom sought by industrial concerns, or if they are the emoluments are such as to induce only the less experienced men to accept the post offered. That discreditable situation should cease. Skilled men are now occupied in advanced work in the laboratories of our universities, university colleges, technical schools, and other research departments. This country is thoroughly equipped with men of ability in chemical and technological science, and it should be the accepted thing for them to find their proper place in the sound organisation of all industries based on high scientific principles. Amongst these must, of course, be included the producers of fine chemicals and drugs. Proof again and again is afforded that the success

of such industries is dependent upon scientific assistance and collaboration, and the services rendered should receive a remuneration consistent with their value. The Government and country should recognise and act upon these considerations; in the manufacture of textile fabrics immediate action is called for, but everywhere the coöperation of organised scientific knowledge should be invited. This has been done in the fullest manner in regard to the medical needs of our army; a similar spirit should appear in our commercial circles.

Influenza or Epidemic Catarrh.

A CONDITION of catarrh of the upper air passages, associated with more or less fever, appears to be raging in London and many parts of the country with almost epidemic intensity. Similar visitations during some parts of the winter months have been the rule, at any rate in recent years. The lay public, in most cases guided thereto by the popular press, labels this condition "influenza" and regards it as a recurring variety of that disease, varying somewhat in its manifestations in successive years. The medical practitioner, pressed for a name to apply to such conditions, as a rule adopts the popular term of influenza as convenient and satisfying, while at the same time if he is a conscientious student of bacteriology he has misgivings about this use of the term, and is careful to explain that it is used in a clinical or popular sense and not as a scientific name. Probably in a damp and changeable climate like that of these islands some form of catarrh of the upper air passages has always been more or less prevalent during the winter months, but a study of the history of epidemic diseases seems to show that in certain years much more severe attacks, sometimes with a large mortality, occur at irregular intervals with epidemic intensity, usually as part of a great pandemic, and to these the name of influenza has been given. The last great pandemic of influenza in 1889 naturally gave a great impetus to the bacteriological study of the disease, and was followed by the discovery of the bacillus influenzae in 1892 by PFEIFFER. Before this discovery the term influenza had solely a clinical significance, and although the terms influenza, coryza, influenza cold, catarrhal fever and febricula were all applied to similar conditions occurring sporadically, or even with mild epidemic incidence at times when no pandemic was raging, there was no suggestion that these conditions had a common bacteriological etiology. After the discovery of Pfeiffer's bacillus it was perhaps too hastily assumed that this organism was the sole cause of these catarrhal fevers, and the protean forms of the condition which occurred in the great pandemic may have seemed to lend some colour to this view. The bacteriology of a so-called common cold is still a vexed question, and many organisms have been incriminated by different observers. There can be little doubt that

an almost identical clinical picture may be induced by different organisms. The same no doubt applies to these epidemic catarrhal attacks with which we are so familiar each winter. It may be doubted whether at the present time there is any genuine influenza present in this country, if by this term we mean the condition produced by Pfeiffer's bacillus. Bacteriological examination of a few cases occurring in any one practitioner's individual experience does not apparently give uniform results, since various organisms may be found, such as the pneumococcus, streptococcus, micrococcus catarrhalis, and even the Friedländer pneumobacillus. It would seem that the time is opportune for a systematic bacteriological examination of numbers of cases occurring in different parts of the country and in different families to determine whether the conditions influencing the epidemic incidence of these winter catarrhal fevers cannot be more clearly established. We should like to know whether there is any preponderance of a particular organism in particular epidemics or in different localities, whether the cases in individual families are infected by the same organism, and what part climatic and telluric conditions play in the development and spread of these catarrhal fevers. Before we can correctly define the condition of influenza some such data are essential, and we should not lightly gird at the practitioner who uses the term influenza in its clinical sense until these data are forthcoming. Some such researches are urgently needed in order to enable the nosologist to classify properly, whether in one group or several, these very common and troublesome conditions, and so to afford us a nomenclature free from confusion.

ARRANGEMENTS FOR MEDICAL CERTIFICATION UNDER THE INSURANCE ACT.—The Irish Insurance Commissioners have now substituted for last year's abortive scheme to establish salaried whole-time certifying medical officers the appointment of certain medical men as salaried part-time officers. This plan is worse for the patient, in that it is impossible for a part-time officer to inquire into the claims with sufficient promptitude. It is more objectionable to the profession for the patients of certain medical men are thus put in a privileged position as to their claims for benefit, while the Commissioners naturally find it difficult to obtain men for the posts. A few medical men have done so. These, however, being mostly in the Poor-law medical service serious difficulties are arising, for the duties of a certifier carry him far out of his Poor-law district, and he is unable to arrange for the care of his patients in his absence. This leads to difficulties as to consultations and extra professional assistance which are especially disturbing in the case of such workhouse medical officers as are also medical advisers, for owing to lack of professional assistance they will be unable to perform operations in workhouse hospitals, and operation cases therefore will have to be sent to Dublin or other large town. The matter has been brought before the Local Government Board by the Irish Medical Committee. Meanwhile the guardians of the Birr union have called for the resignation of such officers as have accepted posts which necessitate their leaving their own districts.

Annotations.

"Ne quid nimis."

THE FOOD-SUPPLY OF THE GERMAN PEOPLE.

IN view of the Prime Minister's spirited utterance in the House of Commons on Monday last, the special article which appeared in our columns of Feb. 20th on the Food-Supply of the German People will receive additional interest. This article, from a Special Correspondent in a Neutral Country, was an abstract of a pamphlet of nearly 200 pages, published at the end of last year under the editorship of Dr. Paul Eltzbacher, acting Rector of the Berlin High School, as an authoritative statement on the food-supply of the German people and the supposed British plan to starve them. No such plan has been formulated, and the present position was brought by the Germans upon themselves. Mr. Asquith has now explained that the German declaration (in regard to submarines) substituted indiscriminate destruction for regulated capture. "Her opponents," he added, "are therefore driven to frame retaliatory measures in order to prevent commodities of any kind from reaching or leaving Germany." The general impression conveyed by our article was that, on the whole, the internal resources of Germany would meet the food requirements of the people for some time to come, provided that a strict economy was practised and that every possible food material was requisitioned. The report represents the collected work of eminent experts, economists, and physiologists, and the inquiry took four months to complete. There is apparently no reference in definite terms in the report as to how long Germany can stave off starvation under the strict economic methods enjoined, but in dealing with the deficit, due chiefly to the cutting off of imports, it is stated that "with every day of continuance on present lines our deficit is increasing, and if no change is made for six months the deficit of available protein for the following six months will be increased to 50 per cent. This is the seriousness of the position." The war has already lasted seven months, and it is not likely that the drastic provisions recommended in the report can have found a complete practical adoption. Meantime the retaliatory measures recently voiced by Mr. Asquith on behalf of the Allies will not improve matters.

MEDICO-LEGAL POINTS IN CONNEXION WITH THE NEW BRITISH PHARMACOPOEIA.

So far as we are aware no serious results have as yet occurred owing to differences between the new British Pharmacopœia and the edition which was in force up to Dec. 31st of last year. That such results might happen in conceivable circumstances is clear. And Mr. Wippell Gadd, in the course of an interesting paper read before the Medico-Legal Society recently, discussed the position of the druggists in making up a prescription of a medical practitioner who has omitted to observe a change of formula brought about by the new issue. Mr. Gadd illustrated his point by referring to *strophanthus*. It was recommended in 1890 that tincture of *strophanthus* should be of the strength of 1 in 20, but in the Pharmacopœia of 1898 this was reduced to 1 in

40, with a recommended dose of 5 to 15 minims. The new Pharmacopœia substitutes for this a strength of 1 in 10 with a dose of 2 to 5 minims,¹ and it is not necessary to refer to recommendations made for lowering rather than raising the standard of strength in order to point out that a medical man who wrote out a prescription including tincture of *strophanthus* having the old standard in his mind might find himself in very serious circumstances if a druggist made up the prescription as on the face of it he ought to do. Dealing with the question what should be the conduct of the dispenser who recognises the error of the practitioner, Mr. Gadd submits the suggestion that the making up and selling of a prescribed medicine is not legally a sale of drugs such as the Sale of Food and Drugs Acts contemplate, but is rather a contract to make up the medicine with an implied condition that the pharmacist will translate the prescription and produce the medicine in accordance with what appears to him in the light of his technical training and experience to be the intention of the prescriber. We are in accord with Mr. Gadd to the extent that the druggist is certainly neither obliged to dispense a medicine in a form which he knows to be dangerous, nor justified in doing so. How far he ought to translate a prescription and make up a medicine in accordance with what he believes to be the prescriber's intention is a different matter. To raise the question and set right an error, particularly where a mistake has arisen from an obvious cause, is comparatively simple in these modern days, and a telephone message would settle the doubt at once in a large proportion of the cases likely to arise. Some such course as this would be in agreement with the recommendation referred to by Mr. Gadd, which is to be found in the preface to the Pharmacopœia, where it is pointed out that the medical practitioner must exercise his judgment in respect of the amount of any therapeutic agent that he may prescribe, with the addition: "Where, however, an unusually large dose appears to be rescribed, it is the duty of the pharmacist or dispenser to satisfy himself that the prescriber's intention has been correctly interpreted." Mr. Gadd's criticism of this is that it does not affect the legal question. No serious legal question, however, seems likely to arise. No Act of Parliament could ever be interpreted as imposing upon a pharmacist the obligation knowingly to hand to his customer a bottle of medicine inscribed with instructions to take it in dangerous quantities, and there is nothing in the Sale of Food and Drugs Acts or in the decisions under them to justify such a suggestion. Under Section 6 of the Act of 1875 "No person shall sell to the prejudice of the purchaser any article of food or any drug which is not of the nature, substance, and quality of the article demanded," and any prosecution under this Act would have to come within the provisions quoted. Now, a person handing over a prescription to be made up could hardly be deemed to have demanded something in which, without his knowledge, an excessive quantity of a dangerous ingredient was recommended, or to be prejudiced by getting something less likely to injure the patient; while the druggist can avoid any risk or liability which he might incur by varying the precise terms of the prescription, if he chooses to refer the matter back to the physician who prescribed. Let us hope, however, that cases such as

¹ THE LANCET, Jan. 9th, 1915, p. 80.

those suggested will but rarely occur. They may do so without any negligence of the prescribing practitioner in connexion with the habit of some members of the public who again and again make use of old prescriptions long after the occasion for which they were given, and perhaps even hand them to their friends. When any such person suffers by causing a prescription given in or before 1914 to be made up under the new Pharmacopœia interesting questions, not so much of law as of who was in fact guilty of negligence, may arise. Meanwhile, as we have already pointed out, there are differences between the new Pharmacopœia and the old, among which the case of tincture of *strophanthus* has been selected as a striking example, and most medical men and druggists will by now have carefully noted them. They include the altered strength of tincture of *nux vomica* and of tincture of opium, of which the former has passed from Part I. to Part II. of the schedule relating to poisons, whereas the latter, under the officially recognised title of *laudanum*, finds itself in Part I. owing to an increase of the percentage of morphine which it must contain.²

COUNTY COUNCILS AND PUBLIC HEALTH MATTERS.

A PAPER on this subject, read by Dr. J. C. Thresh at a meeting of the County Councils Association on Feb. 23rd, deserves close attention from local authorities concerned with public health administration. Taken as a whole, this administration in England and Wales at the present time is full of anomalies, unwieldy, and often needlessly complicated. The duties and mutual relation of officers in the public health service need much revision and consolidation before public medical work can be brought into any sort of system which is theoretically defensible; while a reconstitution of the local bodies themselves and of the areas over which they have jurisdiction must also be in the forefront of any comprehensive reform. Dr. Thresh realises, however, that sweeping proposals for new local government legislation, for the establishment of a Ministry of Health, or for the consolidation of public medical services are unlikely to make progress whilst the country is at war or remains dominated by the consequences of war. Meanwhile he relies upon the British capacity for adjustment and compromise, and invites county councils to consider whether they themselves are making the best use of their present powers and opportunities. In all counties, it is urged, the several medical services should be so organised, under the headship of the county medical officer, that the various departments for school medical work, maternity and infant welfare, tuberculosis, general medical inspection, and possibly also for laboratory work, are in each case efficiently staffed and equipped. There is probably room for better organisation of this kind even in the large English counties, while some of the smaller need to join with their neighbouring county councils or boroughs if the various duties now put on the county authorities are to be properly carried out. Such a process of organisation might well precede application to Parliament for new powers, particularly for powers to enable the county councils to coerce the local authorities of their constituent districts. The sanitary district of the

Public Health Acts remains the administrative unit for much essential public health work, some of it particularly difficult and thankless. Medical officers of health of these districts have the primary responsibility for dealing with outbreaks of infectious disease, the survey of sanitary conditions, the closure of unhealthy dwellings, and many other details of daily work for the health and amenities of their areas. These responsibilities have increased and become more complicated, and the district medical officer of health often needs to be able to turn to other persons in authority for advice and assistance. Dr. Thresh considers that the county staff can give greater aid to progress in this way by acting as advisers than by attempting to dominate as supervisors; leading rather than driving has given the community the most benefit in the past and offers most hope for the future. The question of remodelling public health administration bristles with difficulties, but there will be general agreement that the prospect of effective reforms at a later date should not prejudice local authorities in any efforts to make the best use of the powers and opportunities which they already possess.

EXTRACTION OF A BULLET FROM THE BLADDER BY THE URETHRA.

THE arrest of a bullet in the bladder must be rare, for the projectile must have sufficient force to penetrate the pelvis and not more than sufficient to carry it into the bladder. This is an exceptional combination of conditions, for projectiles which enter the bladder usually pass through it. At a meeting of the Académie de Médecine of Paris on Jan. 26th M. George Luys reported a case in which he removed by the urethra a bullet which had lodged in the bladder. The patient was a soldier, aged 33 years, who, while firing in the lying-down position, was shot in the centre of the right buttock on Nov. 17th, 1914. Supported by two comrades he was able to walk to the ambulance station, a distance of 4 kilometres. As there was complete retention of urine he was catheterised and bloody urine was withdrawn. For five days he passed spontaneously urine of this character, and for two days bloody stools. He then showed symptoms of a foreign body in the bladder. When he attempted to micturate, especially at the time of defæcation, the stream of urine was suddenly arrested, and it was necessary to pass a catheter in order to push back into the bladder a body in the posterior urethra. He was examined by M. Luys on Dec. 17th, when he presented the following symptoms pointing to foreign body in the bladder. 1. Complete inability to micturate in the standing position, micturition being possible only when lying down. 2. Sudden arrest of the stream with pain at the end of the penis. 3. Sometimes after the effort of defæcation the foreign body entered the urethra, but was easily made to return to the bladder by raising the pelvis. There were no symptoms of cystitis; the urine was merely a little cloudy on emission. The wound in the buttock had healed, leaving a scar 0.5 centimetre in diameter. A radiogram showed a bullet in the middle line behind the symphysis with the point directed downwards. With the cystoscope the bullet was seen in a depression on the right side of the bladder. The point was directed to the left and downwards behind the plane of the ureters. The bullet was brilliant and did not appear to be encrusted with salts. Its

² THE LANCET, Jan. 9th (p. 83) and 30th (p. 192), 1915.

removal was urgently necessary. The only method previously used to accomplish this end was suprapubic cystotomy, but the invention of M. Luys's cystoscope with direct vision opened the prospect of removal *per vias naturales*. The cystoscope was passed and the bullet was seized with forceps passed down the tube and removed with the latter. It proved to be a deformed German bullet. There was a slight calcareous deposit in its grooves.

DRUG FUND SHORTAGE IN LONDON.

THE London Insurance Committee on Feb. 25th considered the position of the drug fund, which amounted, it was reported, to about £140,000, while the total demand would be approximately £193,000. In the discussion it was suggested that the deficiency of £53,000 was due to excessive prescribing by practitioners, but Dr. B. A. Richmond, the secretary of the Panel Committee, pointed out that at the present rate at which excess was being found by the Panel Committee in its investigations into prescribing no sum even remotely approaching £53,000 would be refunded to the drug fund, even when all the allegations of excess had been examined. Dr. Richmond urged that a mistake had been made by the Government in basing the drug fund on the Plender Report—itsself founded upon conditions of contract practice which bore no resemblance to those obtaining under the National Insurance Act. Under the present scheme large numbers of women received benefit, and persons suffering from or predisposed to tuberculosis, who under contract practice were excluded, caused under the Insurance Act a heavy drain upon the drug fund in respect of specially expensive articles. The committee decided to call the attention of the Insurance Commissioners to the shortage which had arisen in spite of the action taken in regard to allegations of excessive prescribing, and to ask that steps should be taken to ensure that the chemists receive adequate remuneration for the drugs and appliances supplied by them during 1914.

THE OPEN-AIR TREATMENT OF ACUTE PNEUMONIA.

A STRONG plea for the open-air treatment of acute pneumonia has been made by Dr. George E. Rennie in the *Medical Journal of Australia*. He points out that not only is the imperfect aeration of the blood an indication for the supply of as much fresh pure air as possible, but that also the bacterial content of the air of the best ventilated room or ward is always much higher than that of the outside fresh air. The air of hospital wards is likely to be laden with numerous pathogenic microbes. In such an atmosphere the patient may acquire a secondary infection. At any rate, the conditions are favourable to the growth of the pneumococcus. Further, the air of the ward is laden with organic impurities which must impair the oxygenating power of the respired air. Hence open-air treatment is the most rational procedure. It used to be the custom at the Royal Prince Edward Hospital, Sydney, to surround the patient suffering from pneumonia with curtains to keep off draughts, and, incidentally, to prevent the access of much fresh air. When he became cyanosed oxygen was administered, and when the heart began to fail alcohol, strychnine, and digitalis were used. For the last seven years Dr. Rennie's practice at this hospital has been to treat all cases of acute pneumonia in the open both by day and night. More recently

this has become the universal practice in the hospital, although at first there was prejudice against it. This is important, as it shows that the other physicians have been convinced of the value of the treatment. However, comparison of the mortality statistics before and after the introduction of the treatment does not show any advantage. On the contrary, the mortality for the six years before the introduction was slightly lower than the mortality after it—14·4 against 15·3 per cent. But Dr. L. Teece, the house physician who analysed the records, says: "It was but rarely that pneumonia of itself killed a healthy adult, in whatever manner he was treated, as in practically every fatal case some other factor turned the scale against the patient." A perusal of the histories convinced him that the cases treated by the open-air method more quickly reached a state of comparative comfort, were less subject to post-critical rises of temperature, and showed more rapid resolution than those treated by the old method. Dr. Teece examined minutely the histories of 60 cases before the introduction of the open-air treatment and compared them with 60 cases treated after its introduction. In the former the average duration of the pyrexial period was 11·4 days, the maximum 52 days, and the minimum 3 days. In the latter the corresponding figures were 9·9 days, 34 days, and 4 days. Dr. Rennie adds that "these cold statistics," although they bear out the view that the open-air treatment is an improvement, do not bring out the facts which have been learned by experience, that the patients show much less cyanosis and distress in breathing, that oxygen is rarely necessary, and that unless there is some cardiac complication heart tonics are not required. The patients sleep better and sedatives are rarely necessary. The tongue is cleaner, the appetite is better, and convalescence is rapid. Patients who on admission were extremely ill, some with puerperal complications, recovered rapidly—cases which when treated on the old lines would have been considered inevitably fatal.

PUBLIC HEALTH IN BRITISH COLUMBIA.

THIS province of the Canadian Dominion is an example of the wonderful development that is taking place in the Greater Britain beyond the seas, a development that depends primarily on increase in population. At the last census in 1911 British Columbia had more than doubled the population of 1901; its largest city, Vancouver, had almost quadrupled its numbers in the same period. These rapid developments, however satisfactory from a commercial and industrial point of view, are associated with public health problems that are far more important in their consequences and more difficult to deal with successfully than is commonly appreciated by the authorities who have the control of finance and administration. The report of the Department of Public Health for the province is a document of three pages in length, which seems exiguous for a population of some 400,000 that has grown with the remarkable rapidity just mentioned. No detailed statistics are furnished and very few diseases are referred to. Tuberculosis is the most fatal disease, having caused 422 deaths, of which 295 were due to pulmonary consumption. The Department of Agriculture is endeavouring to stamp out the disease in dairy herds. Notification of tuberculous cases is compulsory, but apparently is not universally carried out. Propagation is

considered to be largely due to the western habit of promiscuous expectoration, which persists in spite of an Order in Council issued in 1901. There were about 700 cases of typhoid fever and 85 deaths, mostly occurring in two districts where considerable railroad construction is being carried on. It is, however, very satisfactory to find that contractors for public works have perceived the economic value of sanitary measures; the camps of the experienced contractor are clean and sanitary, with proper arrangements for storing food, protection from flies, &c., adequate latrines, and good water-supply, whereas those of the inexperienced contractor are the reverse. The former has learned the lesson of cleanliness and its value; the latter should be made to feel his responsibility for cases of sickness resulting in his camp. Infectious diseases have not prevailed to any great extent. Water-supply is a matter of some difficulty, not as regards quantity, but purity. Many towns have outgrown their sewage disposal works, and many waterways from which drinking supplies are derived have become polluted. There are thus many public health problems that are not at all easy of solution, even in a country and climate as favoured, and a population as little crowded, as British Columbia. At a meeting of the health officers of the province in the summer the prevalence of tuberculosis was deplored and sanatorium treatment advocated. Dr. Arthur considered that the time had now arrived when the province should be divided up into districts, each provided with a Government health officer, devoting his whole time to the work. Excellent papers were contributed by Dr. Underhill on sanitary legislation in reference to new buildings, by Mr. W. T. Donald on matters of dairy sanitation, and by Mr. A. G. Dalzell on sewage disposal. School medical inspection was dealt with in an interesting address by Dr. T. V. Hunter. This comparative innovation is passing through the same stages in the extreme west of the Western Hemisphere as it has done in England. At first it was looked on with disfavour, and had only friends among medical men and workers among the poor; then the teachers, and later the parents and the general public, were won over. The value of the school nurse has come to be thoroughly recognised. The meeting of the medical health officers at Vancouver in June, 1914—the first of the kind—was a great success and will, no doubt, be repeated.

A POSSIBLE DANGER IN CONNEXION WITH THE METRIC SYSTEM.

THE introduction of the metric system into the British Pharmacopœia is satisfactory as tending towards internationalism of medical science. It is, however, essential that all dispensing chemists should familiarise themselves with its practical employment and provide themselves with the necessary weights and measures, or many serious errors may occur. That this is no imaginary danger is exemplified in an article by Mr. Martin I. Wilbert, of the Division of Pharmacology, Hygienic Laboratory, United States Public Health Service.¹ Touching on the subject of adulteration and variations in strength of drugs widely used in household remedies, Mr. Wilbert first quotes the Dean of the Massachusetts College of Pharmacy as stating that a "very large proportion of technical

adulteration is due to carelessness or ignorance on the part of the retail pharmacists," and explains the nature of this "carelessness or ignorance" by a statement of the Food and Drug Commissioner for South Dakota, who says that "many of the variations of preparations from the official standards are due to the fact that pharmacists make errors in transposing from the metric system to apothecaries' and avoirdupois weights and measures and the use of incorrect weights and measures or using volume and weight indiscriminately." Such errors in transposing are very easily made, and stringent measures should be taken, it seems to us, to prohibit the introduction of any such source of error in dispensing a prescription as the transposing of it from one set of formulæ to another. Until such time as the metric measures shall have entirely displaced the older forms, as they will undoubtedly do on the score of their all-round superiority in course of time, it should be made incumbent on every pharmacist to dispense any prescription without transposition in the form in which it is written. Most of the best class of dispensing chemists have long been equally familiar with both, and prepared to use either as required. It is not with them that the danger lies, but with those who have hitherto had no occasion to use the metric system. It seems desirable that the pharmacist should have in front of him a complete table of equivalents which now generally appears in pharmaceutical books. The matter certainly demands careful consideration.

AMONG the candidates who have been recommended by the Council of the Royal Society for election as Fellows of the society are four members of the medical profession, Professor F. W. Andrewes, pathologist to St. Bartholomew's Hospital; Dr. Walter Morley Fletcher, secretary of the Medical Research Committee under the National Insurance Act; Dr. James Mackenzie, physician to the Cardiac Department of the London Hospital; and Dr. C. S. Myers, director of the psychological laboratory in the University of Cambridge.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

—At the annual meeting of governors Sir George Hare Philipson was unanimously re-elected vice-chairman of the Court. Professor R. Howden, who has just been elected President of the Anatomical Society of Great Britain and Ireland, presented the annual report of the Council to the Court of Governors, which showed the work of the College during the Epiphany and Easter terms of 1914 to have been quite satisfactory, but in consequence of the war no less than 58 full-time and 2 part-time students have now joined the forces. But notwithstanding the war, the entry of first-year students during 1914 numbered 42, as compared with 34 in the previous year. Most of the clinical teachers of the College are attached to the 1st Northern General Hospital, and three or four are serving with the colours. Just before the close of the financial year the legacy of £10,000 was received from the executors of the late Miss Emily Matilda Easton, and the principal mortgage on the building—viz., one for £8900—was paid off, and since the close of 1914 the remaining mortgages, amounting to £1225, have been discharged. The treasurer of the College, Mr. Cecil Cochrane, in presenting a statement of the financial situation, said that up to the time of the outbreak of war there was every reason to expect a successful year, while the governors were now in the happy position of having the College and land free from all encumbrance, but unfortunately the College had suffered severely in consequence of the war. At the annual meeting of the Council Sir George Hare Philipson was, as we announced in a recent issue, presented with an illuminated address in Latin, congratulating him on the completion of his 50 years' service as professor and lecturer in the College.

¹ United States Public Health Reports, Jan. 29th, 1915, p. 311.

ASYLUM REPORTS.

Dorset County Asylum for the Treatment of Mental Diseases (Annual Report for the Year 1913).—The total number of cases under treatment during the year was 1108, the average daily number resident being 944. There were admitted 167 cases, of which 35 were not first admissions. Dr. P. W. Macdonald, the medical superintendent, remarks on the fact that for several years past there has been a very high percentage of the excited type compared with the depressed class. In 1913 there were admitted twice as many cases of the excited as of the depressed type. Any explanation of this variation in the class of cases admitted is surrounded with difficulties, and while the age problem and the home environment may play prominent parts, these do not satisfactorily explain the recurring differences in the type of admissions. Less than one-half of the total number were between the ages of 20 and 40, which does not support the view that there are more cases of excitement than depression during this particular period. Two-thirds of the admissions were over 50 years of age, and yet the high proportion of maniacal cases was maintained. The number discharged was 96, with a recovery rate on the direct admissions of 48.9 per cent., which is much above the average. Good results continue to follow the practice of treating all acute cases in the solarium. The deaths amounted to 69, making a percentage of 7.31 on the average daily number resident. Dr. Macdonald notes that the causes of death were all natural, and the only fact of passing interest was the unusual number due to malignant disease.

Wilts County Asylum (Annual Report for the Year 1913).—The total number of cases under treatment during the year was 1192, the average number resident being 1014.3. There were admitted 188 cases, of whom 25 were readmissions. The number received was high, having been exceeded on only two previous occasions, and was 19 above the average for the past ten years. The following were the leading assigned causes of attack: Heredity, 33 per cent.; senility, 11.4 per cent.; mental stress, 18.9 per cent.; alcoholism, 7.4 per cent.; and epilepsy, 6.3 per cent. In no less than 73 of those admitted some cardiac defect existed. The discharges numbered 92, of whom 66 were recovered, making a recovery rate of 35.1. With the exception of four patients all those discharged recovered had a probationary period on trial, and to 17 of those a money allowance was granted. Such grants are a well-recognised aid to completion of recovery, and are much appreciated and undoubtedly of the utmost benefit to the recipients. The deaths amounted to 36, giving a death-rate of 8.1. The cause of death was verified by necropsy in 77.1 per cent. of the cases. Phthisis was responsible for death in 25.3 per cent. of the cases. Dr. Sydney Cole, the medical superintendent, notes that at one time the number of male patients resident was 30 in excess of the authorised accommodation, and at one time the number of female patients was two in excess. In the last report attention was called to the manner in which overcrowding conduces to the prevalence of phthisis. Dr. Cole reports with regret that phthisis has since become even more prevalent, showing with increasing force how urgent is the need for the additional accommodation about to be provided.

Glasgow District Mental Hospital, Gartloch (Annual Report for the Year 1913-14).—The total number of cases under treatment during the year was 1016, the average daily number resident being 774.2. There were admitted 263 cases, of whom no less than 67.67 per cent. were hopelessly incurable. The abuse of alcohol heads the list of causes of insanity in the admissions. In 49 cases alcohol is put down as the determining cause, and in combination with syphilis or lactation in other 10 cases, making a percentage of 22.4 on the admissions. Syphilis alone or in combination with alcohol is responsible for at least 23 cases. Of the admissions 198 unselected cases were tested for syphilis by the Wassermann reaction of the blood. Thirty-eight were positive and 130 negative. Two cases of general paralysis gave negative results, but these were not tested as regards their cerebro-spinal fluid. Dr. W. A. Parker, the medical superintendent, comments on the influence of alcohol as an indirect cause of insanity. Of the admissions, the cases in which a history of the abuse or

non-abuse of alcohol by their parents was obtained gave a percentage of parental abuse of alcohol of 51.6, while if those only were considered whose first breakdown took place before the completion of their twenty-sixth year the percentage amounted to 80.6. The number of discharges was 166, with a recovery rate, calculated on the admissions, of 35.3 per cent. There were 76 deaths, making a percentage of 9.8 on the average daily number resident. Tuberculosis was responsible for death in 3.9 per cent. of the cases, which is the lowest percentage ever recorded at this asylum. Active tuberculous disease was present, and contributory to some extent in causing death in 11 other cases besides the three ascribed to tubercle.

James Murray's Royal Asylum, Perth (Annual Report for the Year ending March 31st, 1914).—The total number of cases under treatment during the year was 150, the average daily number on the register being 118.34. The number of admissions was 30, of whom 23 were admitted for the first time. 20 per cent. of the new patients were suffering from a psychosis brought on by alcoholic intemperance, and in only 25 per cent. of these was a history of morbid heredity obtained. In 15 of the 30 patients admitted a hereditary predisposition to insanity or to one of the allied nervous conditions was present. Fifteen were suffering from an incurable form of mental disorder, while in a similar number the probability of recovery was good. The recovery rate for the year was as low as 20.0 per cent. The deaths amounted to 9, making a rate on the daily number resident of 7.6 per cent. The average age at death was 61.1 years, and the average duration of residence was 4 years 6 months. A large percentage of the men patients were engaged daily in working in the gardens. The usual experience is that they become interested in this occupation, and, as can be readily understood, it proves of benefit to the bodily and mental state of the patients.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon Henry Baker Hall has been placed on the Retired List (dated Feb. 19th).

The undermentioned have been granted temporary Commissions as Surgeons in His Majesty's Fleet: Oscar Parkes, Alfred Gregson Williams, James Francis Quigley, and James Douglas Judson.

The following appointments have been notified:—Staff-Surgeons: R. R. Horley to the *Royal Arthur* and R. H. St. B. E. Hughes to the *Sextinel*. Temporary Surgeons: F. C. Blakiston to the *Vivid*, additional, for Devonport Yard; A. E. Iles to Hospital ship *Plassy*; and J. Souter to the *Wildfire*, additional.

ROYAL NAVAL VOLUNTEER RESERVE.

Staff-Surgeon: W. Allan to the *Vivid*, additional, for R.N. Barracks. Surgeon Probationers: P. G. Horsburgh to the *Morris* and H. E. Andrews to the *Mentor*.

ARMY MEDICAL SERVICE.

The undermentioned Colonels to be Surgeon-Generals:—Dated March 1st: Menus W. O'Keefe, C.B., Richard H. S. Sawyer, C.M.G., John C. Culling, William G. Birrell, Francis J. Jencken, and Francis H. Treherne, C.M.G.

The undermentioned Lieutenant-Colonels, from Royal Army Medical Corps, to be Colonels:—Dated March 1st: Robert L. R. Macleod, Gifton G. Adams, James M. F. Shine, Nicholas C. Ferguson, C.M.G., Gerald Cree, Samuel C. Philson, Sydney G. Allen, Philip C. H. Gordon, Llewellyn T. M. Nash, C.M.G., James H. Daly, Henry D. Rowan, Howard Carr, Thomas Daly, Michael J. Sexton, Herbert E. Cree, William H. Starr, Alexander A. Sutton, D.S.O., Michael T. Yarr, Charles H. Melville, James B. Wilson, Frederick W. G. Gordon-Hall, Henry M. Adamson, Tudor G. Lavie, Charles H. Burtchell, C.M.G., John J. Gerrard, John S. Davidson, James Fallon, Charles J. Macdonald, Robert W. Wright, Edwin Eckersley, Denis M. O'Callaghan, George H. Barefoot, C.M.G., Foster R. Newland, Reginald J. Windle, John J. Russell, Thomas du B. Whaite, Henry T. Knaggs, Richard H. Penton, D.S.O., Frederick J. Morgan, Brevet Colonel William H. Horrocks, K.H.S., Charles H. Dale, D.S.O., Hugh C. Thurston, C.M.G., Bertal H. Scott, Oliver R. A. Julian, C.M.G., Eustace A. Burnside, Stuart Macdonald, Brevet Colonel Maurice P. C. Holt, D.S.O., William L. Gray, Edward G. Browne, James C. Morgan, Herbert I. Pocock, Charles R. Elliott, Charles A. Young, John W. Bullen, Benjamin J. Inniss, Stephen F. Clark, Edward M. Hassard,

Sir William B. Leishman, C.B., K.H.P., James Thomson, Gerald T. Rawnsley, Alfred P. Blenkinsop, John Girvin, Brevet Colonel Anthony John Luther, William Hallaran, Samuel G. Moores, Thomas B. Beach, Coryndon W. R. Healey, John H. E. Austin, William T. Mould, Alfred W. Bewley, and Robert J. Copeland.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel John Donaldson to be placed on retired pay (dated Dec. 31st, 1914).

The undermentioned Majors to be Lieutenant-Colonels: Edward W. Slayter (dated Dec. 31st, 1914). Hugh S. Thurston (dated Feb. 8th), and Lancelot P. More (dated Feb. 22nd). Dated March 1st: Theophilus P. Jones, Albert G. Thompson, George A. Moore, Richard C. Lewis, Henry W. H. O'Reilly, Edgar H. Condon, Harold W. K. Read, Frederick M. Mangin, Charles E. Pollock, William J. Taylor, Bel W. Longhurst, Ferberd R. Buswell, Frank A. Symons, D.S.O., Charles T. Samman, Thomas H. J. C. Goodwin, D.S.O., Alfred E. C. Keble, Denis J. Collins, John B. Anderson, James R. McMunn, Harold V. Pryme, Alfred E. Master, George Dansey-Browning, Ernest S. Clark, Kennet B. Barnett, Arthur C. Fox, D.S.O., Sebert F. St. D. Green, Michael Boyle, Percy Evans, Claude K. Morgan, George St. C. Thom, John P. Silver, Brevet Lieutenant-Colonel William S. Harrison, Harry A. L. Howell, Douglas Lawson, Charles W. Profeit, Frederick Kiddle, Henry E. Staddon, Samuel J. C. P. Perry, Lionel F. Smith, Robert J. Blackham, C.I.E. (and to remain seconded), Henry W. Grattan, John Grech, St. John B. Killery, Septimus H. Fairrie, George T. K. Maurice, C.M.G., Francis E. Gunter, John H. Campbell, D.S.O., John V. Forrest, John C. B. Statham, Edwin C. Hayes, Edwin T. F. Birrell, C.M.G., Brevet Lieutenant-Colonel Ernest W. Bliss, Percy J. Probyn, D.S.O., Brevet Lieutenant-Colonel Arthur W. Hooper, D.S.O., Anthony H. Waring, Edward W. W. Cochrane, Arthur H. Morris, Samuel A. Archer, Robert W. Clements, Alexander J. MacDougall, Maurice Swabey, George B. Riddick, Henry Hewetson, George E. F. Stammers, Charles F. Wanhill, Wilfrid E. Hudleston, Martin P. Corkery, Leonard Addams-Williams, Malcolm MacG. Rattray, Thomas H. M. Clarke, C.M.G., D.S.O., Edwin W. P. V. Marriott, Stevenson L. Cummins, Peter Mackessack, Henry L. W. Norrington, D.S.O., John McD. McCarthy, John Poe, Hamilton G. F. Stallard, Ernest Brodribb, Arthur W. N. Bowen, William H. S. Nickerson, V.C., Hubert O. B. Browne Mason, Frederick S. Penny, Brian Watts, Henry G. Martin, Frederick F. Carroll (and to remain seconded), John D. G. Macpherson, William P. Gwynn, Standish de C. O'Grady, Augustus H. O. Young, Ernest A. Bourke, Montagu M. Lowsley, Norman H. Ross, Edgar T. Inkson, V.C., Percy H. Collingwood, Charles J. O'Gorman, D.S.O., Robert S. H. Fuhr, D.S.O., Harold P. W. Barrow, David Harvey, George J. S. Archer, Sydney O. Hall, Alfred E. Weld, James S. Gallie, Francis J. C. Heffernan, Henry Herrick, James Cowan, Austin R. O'Flaherty, Henry B. G. Walton, George B. Crisp, Cecil W. Mainprise, Alec L. Scott, Gerald H. Goddard, John E. Hodgson, Brevet Lieutenant-Colonel Matthew H. G. Fell, William B. Winkfield, Jonas W. Leake, John W. H. Houghton, George M. Goldsmith, Richard H. Lloyd, Brevet Lieutenant-Colonel John M. Sloan, D.S.O., Harry D. Packer, Lawrence Humphry, Frank Ashe, James G. Gill, Thomas C. Lauder, Duncan B. Curme, Herbert S. Taylor, Francis J. Brakenridge, Edmund P. Hewitt, Nathaniel J. C. Rutherford, D.S.O., Gilbert J. A. Ormsby, D.S.O., Horace K. Palmer, Francis J. Palmer, Vincent J. Crawford, D.S.O., Arthur L. A. Webb, Brevet Lieutenant-Colonel Howard Ensor, D.S.O., Robert A. Cunningham, George G. Delap, D.S.O., Harold Simson, William R. Blackwell, Arthur Chopping, Sydney G. Butler, D.S.O., John J. W. Prescott, D.S.O., Arthur O. B. Wroughton, Percy H. Falkner, Henry E. M. Douglas, V.C., D.S.O., Ernest E. Ellery, James W. Langstaff, Leonard Wood, Harold B. Fawcus, Evelyn P. Sewell, Lawrence W. Harrison, D.S.O., Hugh M. Morton, Marcus H. Babington, Horace S. Roch, Frederic Harvey, Henry C. R. Hime, Charles C. Cumming, Charles R. Evans, D.S.O., Harold H. Norman, William A. Woodside, Littleton F. F. Winslow, Otto W. A. Elsner, Arthur A. Seeds, Henry S. Anderson, Langford N. Lloyd, D.S.O., Thomas C. Mackenzie, D.S.O., Edward P. Connolly, and James H. R. Bond.

Temporary Captain Robert Stewart Rodger to be temporary Major (dated Feb. 27th).

The undermentioned temporary Lieutenants to be temporary Captains:—Dated Feb. 27th: Bertie Burnett Ham and Franke Chamberlain Hart-Smith.

INDIAN MEDICAL SERVICE.

The King has approved the promotion of the following Officers: To be Brevet Lieutenant-Colonel: Major Frank Wall (dated May 31st, 1914). Lieutenants to be Captains: Dated July 29th, 1914: Denis Fitzgerald Murphy and Leon Francis Brandebourg.

The promotion of Major Andrew Murphy to his present rank is antedated from June 27th, 1913, to Dec. 27th, 1912.

The King has approved the grant of temporary rank to the undermentioned:—To be Major: Colonel George Francis Rowcroft, D.S.O., Indian Army, retired (dated Jan. 8th). To be Lieutenants: Vinayak Mahadeo Phatak (dated Oct. 8th, 1914), Hira Singh Anand (dated Nov. 26th, 1914), and Henry Charles Semon (dated Jan. 7th).

The King has approved the retirement of the undermentioned officers: Lieutenant-Colonel Arthur Charles Younan (dated Jan. 1st) and Lieutenant-Colonel Vivian Godfrey Drake-Brockman (dated Feb. 13th).

TERRITORIAL FORCE.

Royal Army Medical Corps.

The undermentioned Captains to be Majors (temporary): Percy W. Thompson and John R. Holmes.

London Mounted Brigade Field Ambulance: Ernest George Thornton Poynder to be Lieutenant.

2nd South Midland Mounted Brigade Field Ambulance: Henry John Blackler to be Lieutenant.

3rd Home Counties Field Ambulance: Major Stanley A. Coad to be Lieutenant-Colonel (temporary). Captain James Barkley to be Major (temporary).

1st West Riding Field Ambulance: Lieutenant Henry Norman Goode to be Captain (temporary).

3rd London General Hospital: Captain Dennis Embleton is seconded. Philip Withers Green to be Lieutenant.

3rd Southern General Hospital: James Andrew Gunn to be Lieutenant.

South Wales Mounted Brigade Field Ambulance: Major Herbert Jones to be Lieutenant-Colonel (temporary).

3rd East Anglian Field Ambulance: Major George Alexander Troup to be Lieutenant-Colonel (temporary).

3rd East Lancashire Field Ambulance: Henry Wilson to be Lieutenant.

1st Welsh Field Ambulance: To be Lieutenants: Henry Mills, Alexander Edward Mackenzie, and Lieutenant Arvor Jones, from Attached to Units other than Medical Units.

3rd Welsh Field Ambulance: The undermentioned Captains, from Attached to Units other than Medical Units, to be Captains: Frederick A. W. Drinkwater and Percy C. P. Ingram. Lieutenant Peyton T. Warren, from Attached to Units other than Medical Units, to be Lieutenant.

1st Scottish General Hospital: George Stuart to be Captain, whose services will be available on mobilisation.

Lowland Casualty Clearing Station: Lieutenant-Colonel Peter F. Shaw resigns his commission on account of ill-health, and is granted permission to retain his rank and wear the prescribed uniform.

2nd Home Counties Field Ambulance: Captain Antony Alexander Martin, from 1st Home Counties Field Ambulance, to be Captain.

4th London Field Ambulance: Major Arthur E. Jerman to be Lieutenant-Colonel (temporary).

Sanitary Service: Captain Leonard R. Toswill, from 3rd East Anglian Field Ambulance, to be Sanitary Officer, East Anglian Reserve Division.

Attached to Units other than Medical Units.—Major John Griffiths, from South Wales Mounted Brigade Field Ambulance, to be Major. Lieutenant Robert Donald to be Captain. To be Lieutenants: Michael Brannan (late Cadet, Durham University Contingent, Senior Division, Officers Training Corps), Cecil Randle Harper, and Joseph Loughheed Baskin.

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

Captain James R. Chalmers, from the 4th Scottish General Hospital, to be Captain.

Lieutenant Joseph H. Churchill, from Attached to Units other than Medical Units, to be Lieutenant.

DEATHS IN THE SERVICES.

Deputy Surgeon-General Arthur Rudge, late A.M.D., recently, at Plymouth, aged 89 years. He received his first commission in 1850 and retired on half-pay in June, 1875.

SHORT WEIGHT IN BREAD.—In view of recent increases in the price of bread the London County Council is taking steps to make it widely known in the county that purchasers may demand that bread shall be weighed in their presence; that it is not sufficient to ask for a "loaf," but that 4lb. or 2lb. loaves should be asked for. A limited investigation has shown that over 7 per cent. of loaves purchased in bakers' shops and 46 per cent. of loaves purchased at provision dealers' shops are under weight. 58 per cent. of loaves delivered at houses are under weight. The Public Control Committee of the Council is making representations to the Board of Trade as to the need for action to be taken in the public interest, having regard to the importance of bread as a principal article of food among the very poorest.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last census, 8916 births and 7089 deaths were registered during the week ended Saturday, Feb. 27th. The annual rate of mortality in these towns, which had been 20.1, 18.9, and 20.7 per 1000 in the three preceding weeks, fell in the week under notice to 20.4 per 1000 of their aggregate population, estimated at 18,134,239 persons at the middle of 1914. During the first eight weeks of the current quarter the mean annual death-rate in these towns averaged 19.4, against 20.2 per 1000 in London. The annual death-rate last week ranged from 5.5 in Smethwick, 6.3 in Ilford, 9.7 in Leyton, 10.0 in East Ham, and 10.6 in Hornsey, to 29.8 in Northampton, 31.6 in Darlington, 31.8 in Blackpool, 32.9 in Gloucester, and 42.5 in Cambridge.

The 7089 deaths from all causes were 102 fewer than the number in the previous week, and included 617 which were referred to the principal epidemic diseases, against 511 and 607 in the two preceding weeks. Of these 617 deaths, 306 resulted from measles, 111 from whooping-cough, 75 from infantile diarrhoeal diseases, 72 from diphtheria, 38 from scarlet fever, 13 from enteric fever, and 2 from small-pox. The mean annual death-rate from these diseases was equal to 1.8 per 1000, and was 0.1 per 1000 above that recorded in the previous week. The deaths attributed to measles, which had been 210, 207, and 263 in the three preceding weeks, further rose to 306 last week, and caused the highest annual death-rates of 3.2 in Acton, 3.4 in Northampton, 3.5 in Tottenham and in Stockton-on-Tees, 3.9 in Gateshead, 4.3 in Enfield, 4.4 in Wolverhampton, 7.9 in Darlington, and 8.1 in Cambridge. The deaths referred to whooping-cough, which had increased from 76 to 135 in the six preceding weeks, fell to 111 last week; the highest recorded death-rates from this cause were 1.4 in Bristol and in Warrington, 1.6 in Blackburn, 1.7 in Tynemouth, 2.1 in Bootle, 2.3 in Reading, and 2.5 in Merthyr Tydfil. The fatal cases of diarrhoea and enteritis (among infants under 2 years), which had been 68, 70, and 80 in the three preceding weeks, fell to 75 last week, and included 13 in London, 7 in Liverpool, 6 in Manchester, and 5 in Birmingham. The deaths attributed to diphtheria, which had been 72, 66, and 80 in the three preceding weeks, fell to 72 last week, of which 21 belonged to London, 10 to Liverpool, 4 to Manchester, and 3 each to Portsmouth and Cardiff. The deaths referred to scarlet fever, which had been 22, 27, and 32 in the three preceding weeks, further rose to 38 last week; 6 deaths were registered in London, 5 in Manchester, 3 in Leeds, and 2 each in West Ham, Portsmouth, Ipswich, Newcastle-on-Tyne, and Rhondda. The fatal cases of enteric fever, which had been 17, 16, and 17 in the three preceding weeks, fell to 13 last week, and included 3 in London and 2 in Newcastle-on-Tyne. The 2 deaths from small-pox belonged to the Metropolitan Borough of Fulham.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 5035 to 3165 in the 13 preceding weeks, had further decreased to 3041 on Saturday last; 302 new cases were admitted during the week, against 365, 368, and 295 in the three preceding weeks. These hospitals also contained 1571 cases of diphtheria, 239 of measles, 64 of enteric fever, 14 of whooping-cough, and 5 of small-pox. The 1835 deaths from all causes in London were 33 in excess of the number in the previous week, and corresponded to an annual death-rate of 21.2 per 1000. The deaths referred to diseases of the respiratory system, which had been 497, 455, and 459 in the three preceding weeks, further rose to 476 in the week under notice, and were 233 above the number registered in the corresponding week of last year. The deaths from influenza numbered 83, having been 44, 56, and 60 in the preceding three weeks.

Of the 7089 deaths from all causes in the 96 towns 190 resulted from different forms of violence and 472 were the subject of coroners' inquests, while 1850 occurred in public institutions. The causes of 55, or 0.8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 69 other smaller towns. Of the 55 uncertified causes, 16 were registered in Birmingham, 14 in Liverpool, 3 in Bolton, and 2 each in London, Barrow-in-Furness, and Gateshead.

HEALTH OF SCOTCH TOWNS.

IN the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1188 births and 955 deaths were registered during the week

ended Saturday, Feb. 27th. The annual rate of mortality in these towns, which had been 24.1, 23.1, and 22.8 per 1000 in the three preceding weeks, further fell to 21.2 per 1000 in the week under notice. During the first eight weeks of the current quarter the mean annual death-rate in these towns averaged 22.8, against 19.4 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 9.4 in Clydebank, 9.5 in Hamilton, and 11.3 in Motherwell, to 24.0 in Leith, 24.3 in Kirkcaldy, and 30.9 in Dundee.

The 956 deaths from all causes were 68 fewer than the number in the previous week, and included 131 which were referred to the principal epidemic diseases, against 122 and 139 in the two preceding weeks. Of these 131 deaths, 89 resulted from whooping-cough, 11 each from scarlet fever and diphtheria, 10 from infantile diarrhoeal diseases, 8 from measles, and 2 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2.9, against 1.8 per 1000 in the large English towns. The deaths attributed to whooping-cough, which had been 86, 81, and 97 in the three preceding weeks, fell to 89 last week, and included 45 in Glasgow, 20 in Dundee, 5 each in Edinburgh and Greenock, and 4 each in Paisley and Kilmarnock. The deaths referred to scarlet fever, which had been 17, 8, and 10 in the three preceding weeks, were 11 last week, of which 5 were registered in Glasgow and 2 each in Edinburgh and Aberdeen. The fatal cases of diphtheria, which had been 13, 6, and 8 in the three preceding weeks, further rose to 11 last week, and included 4 deaths in Dundee, 3 in Glasgow, and 2 in Edinburgh. The deaths of infants (under 2 years) attributed to diarrhoea and enteritis, which had been 16, 14, and 10 in the three preceding weeks, were again 10 last week, of which 4 occurred in Glasgow, 3 in Dundee, and 2 in Paisley. The deaths referred to measles, which had been 13, 11, and 13 in the three preceding weeks, fell to 8 last week, and included 6 in Glasgow. The fatal cases of enteric fever were registered in Glasgow and Greenock.

The deaths referred to diseases of the respiratory system, which had been 302, 278, and 265 in the three preceding weeks, further declined to 235 in the week under notice, but were 119 in excess of the number recorded in the corresponding week of last year. The deaths attributed to violence numbered 34, against 35 and 26 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

IN the 27 town districts of Ireland with an aggregate population estimated at 1,212,380 persons at the middle of this year, 647 births and 642 deaths were registered during the week ended Saturday, Feb. 27th. The annual rate of mortality in these towns, which had increased from 24.0 to 26.5 per 1000 in the five preceding weeks, further rose to 27.6 per 1000 in the week under notice. During the first eight weeks of the current quarter the mean annual death-rate in these towns averaged 25.8, against corresponding rates of 19.4 and 22.8 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 34.4 in Dublin (against 21.2 in London and 21.3 in Glasgow), 22.8 in Belfast, 26.5 in Cork, 21.5 in Londonderry, 21.7 in Limerick, and 39.9 in Waterford, while in the 21 smaller towns the mean rate was 24.8 per 1000.

The 642 deaths from all causes were 25 in excess of the number in the preceding week, and included 38 which were referred to the principal epidemic diseases, against 44 and 35 in the two preceding weeks. Of these 38 deaths, 18 resulted from whooping-cough, 8 from measles, 6 from diphtheria, 5 from infantile diarrhoeal diseases, and 1 from enteric fever, but not one from scarlet fever or from small-pox. The mean annual death-rate from these diseases was equal to 1.6, against corresponding rates of 1.8 and 2.9 per 1000 in the English and Scotch towns respectively. The deaths attributed to whooping-cough, which had been 13, 17, and 12 in the three preceding weeks, rose to 18 last week, and comprised 11 in Dublin, 6 in Belfast, and 1 in Cork. The deaths referred to measles, which had been 6, 5, and 6 in the three preceding weeks, rose to 11 last week, of which 4 occurred in Belfast, 3 in Portadown, and 1 in Queenstown. The 6 fatal cases of diphtheria, of which 2 were registered in Kilkenny, were 3 in excess of the average in the earlier weeks of the quarter. The deaths of infants (under 2 years) attributed to diarrhoea and enteritis, which had been 10, 13, and 10 in the three preceding weeks, fell to 5 last week, and included 2 in Dublin. The fatal case of enteric fever occurred in Dublin.

The deaths referred to diseases of the respiratory system, which had been 172, 182, and 168 in the three preceding weeks, rose to 187 in the week under notice. Of the 642 deaths from all causes, 180, or 28 per cent., occurred in public institutions, and 14 resulted from different forms of violence. The causes of 32, or 5.0 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the English towns the proportion of uncertified causes did not exceed 0.8 per cent.

INDIA.

(FROM OUR OWN CORRESPONDENTS.)

The Medical Services of Bengal.

THE interest of the medical profession, outside the ranks of the Indian Medical Service, has, as is well known, been the source of considerable anxiety to Government of recent times. This is as it should be, but that the path of the good intentioned is as precarious as ever is clearly shown in the triennial report on the working of the hospitals and dispensaries in Bengal from the pen of Colonel G. F. Harris, Inspector-General of Civil Hospitals. As he says, the period under review (the years 1911, 1912, and 1913) was noticeable for the introduction of an independent medical profession in the presidency. To this end the newly created chair of anatomy in the Medical College, Calcutta, was reserved for them, and in addition three of the house appointments at the Mayo Hospital, Calcutta, and seven similar appointments at the Medical College there were filled by men not in Government service. Well meant as it was, this experiment has not, however, been an unqualified success. The trouble has, it appears, been that the independent members of the medical profession to whom the posts were given have proved just a little too independent. As Government's comment on Colonel Harris's report has it, the experiment failed chiefly owing "to the impatience of discipline shown by the young and inexperienced men appointed." On this point Colonel Harris himself cautiously observes that it is early yet to offer any criticism; but he quotes Lieutenant-Colonel Calvert, principal of the Medical College, who states that the Government's latest endeavour to father the independent medical profession has been received with no enthusiasm and has impeded the smooth working of the College. Colonel Calvert adds that one effect of these appointments has been to increase the cost of hospital expenditure, as the independent men have not the same sense of responsibility and the same knowledge of hospital administration as officers in permanent Government employment. Consequently they are disposed to spend more on diet and dressing materials. With ardour undamped by the unsatisfactory development of this essay in benevolent intention, the Government of Bengal is now watching with great interest the progress of another measure also designed to encourage the independent practitioner. This consists in the association of selected members of the profession with the staff of Government hospitals as honorary surgeons and physicians, who are allowed facilities for consultation at Government hospitals and the use of operating theatres. The experiment at present is only in its initial stage, and so far only eight such appointments have been made.

The Cocaine Conference.

The conference now in progress at Delhi on the question of cocaine smuggling has chosen an opportune time for its deliberations, and it can be wished that the delegates were representative of all provinces of India instead of only Delhi, Punjab, and the United Provinces. For, as in vastly more important matters, the European War is at present the controlling factor in the cocaine trade. German chemists have for some years been the chief suppliers of the Indian market; at first openly, but recently clandestinely. Previous to the placing of cocaine on the prohibited list many native dealers

obtained their supplies direct from German firms, their manufactures being cheaper and more in demand than the English product. After possession and sale were made illegal, direct dealings with manufacturers did not cease entirely, but they are now attended with an amount of risk to the consignee that he is usually unwilling to undergo. He prefers to deal with an intermediary, who, while claiming a large share of the profits, will accept the main chances of detection. And so employees of shipping firms have found a new outlet for their smuggling proclivities.

Ambulance Trains in India.

The following are some details of the ambulance trains now running in India on the following routes:—(1) Poona, Secunderabad, and Southern India; (2) Lucknow and Northern India; (3) Lahore and North-West India. These three trains are completely equipped with everything necessary and requisite for the treatment of our sick and wounded soldiers. Considerable care and consideration have been exercised in the arrangements, and every effort has been made to provide the detailed wants for the comfort of the occupants. The trains were fitted up at the Lahore shops of the North-West Railway, and each comprises nine vehicles vestibuled together and forms a complete hospital on wheels. The make-up of a train is as follows:—

(1) Guard's brake with compartments for the personnel; (2) and (3) open ambulance cars with berths on one side and invalids' cots on the other, each car being provided with bathroom accommodation, &c.; (4) medical officer's headquarters with his assistants' sleeping berths, dining-room, small kitchen, stores, &c.; (5) separate kitchens for Mohammedan and Hindu stores, dispensary, operating-room, and accommodation for assistants; (6) and (7) open ambulance cars like Nos. 2 and 3; (8) a car with compartments opening off side corridor for convalescent cases; (9) brake with luggage compartment for equipment, clothes, &c., also accommodating train staff.

The trains are fitted throughout with electric light and fans, and each car has large water tanks underneath to provide a plentiful supply of water, filters for drinking-water in each carriage, also lockers and cupboards for linen, blankets, &c.

The St. John Ambulance Association in India.

The St. John Ambulance Association headquarters for the winter have been established in a commodious flat in the Khyber Pass Buildings, the Mall, Delhi. These premises have been lent to the Association free of rent by Khan Sahib Haji Baksh Ellahie, C.I.E., principal of the firm of Buksh Ellahie and Co., army contractors, Queen's-road, Delhi.

School of Tropical Medicine.

Good progress is being made with the scheme for the establishment of a school of tropical medicine in Calcutta, with which the name of Sir Leonard Rogers, I.M.S., is so honourably associated. An excellent site has been secured close to the Calcutta Medical College, and the buildings are now going up. The first subscription list shows that Rs.1½ lakhs have already been obtained and another half lakh is practically secured.

Bengali Volunteer Field Ambulance Corps.

The scheme organised by Dr. Sarbadhicari and Mr. Bhupendranath Basu for the formation of a Bengali Volunteer Field Ambulance Corps for active service now has Rs.1,50,000 collected or promised and has registered some 700 volunteers, out of which 200 are to be selected to form the first unit.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Surgery of Gunshot Lesions of Peripheral Nerves.

M. Gosset recently reported to the Société de Chirurgie the results of his own operative intervention in 60 cases of wounds of peripheral nerves by projectiles. Such intervention was determined on in every case only after consultation with competent specialists, and in each case manifest lesions were found. The nerves affected were: radial, 16 times; sciatic, 10; ulnar and median, 8; median alone, 5; external popliteal, 5; ulnar, 4; crural, 4; brachial plexus, 2; internal cutaneous of the arm, 2; internal cutaneous and ulnar, 1; internal cutaneous of the arm and median, 1; anterior tibial, 1. M. Gosset holds that whenever lesion of a peripheral nerve is diagnosed an exploratory incision is absolutely indicated, so that the lesion may be subjected to inspection. This incision can have no ill effects if thorough asepsis is maintained, rubber gloves being always used and drainage avoided. It should be done as promptly as possible when there is freedom from suppuration. Patients thus wounded should remain as short a time as possible in the ambulance, and should be as rapidly as possible sent on to special hospitals where they can be examined and operated on. Early operation is of the first importance, general anaesthesia should be used, and the nerve fully exposed by long incisions. The nerve must first be inspected where it is uninjured above and below the lesion. It must then be freed by dissection and dealt with at the site of the lesion itself. Simple asepsis should be practised and the operative field irrigated from time to time with hot normal saline solution to prevent desiccation of the nerve. Manipulation of the nerve must be practised with especial care and gentleness. The data furnished during operation by sight and touch are of great interest. Similar interest also attaches to the results furnished by electrification of the exposed nerve trunk. The later results of these interventions, however, will require some months before they can be properly estimated.

Vinegar as an Antiseptic.

M. Loir and M. Legangneux in an interesting paper lay stress on the important part played by fresh vegetables in the dissemination of typhoid fever, and have made a study of the value of vinegar as a destroyer of the typhoid bacillus. It has long been known that Eberth's bacillus is susceptible to acidity. In wine it rapidly disappears. Dr. Gaillard has shown that the addition of every kind of alcoholic drink to water results in an almost immediate diminution of the number of contained microbes. All the pathogenic varieties are destroyed by an admixture of equal parts. The typhoid bacillus is more sensitive to white than to red wine, the former being usually more acid. The authors have made numerous experiments to determine the degree of acidity required to destroy Eberth's bacillus in water. They find that 20 grammes of vinegar to a litre of water kills the typhoid bacillus in an hour and five minutes. From this a practical inference may be drawn concerning salads. After washing the salad as usual, detaching each leaf, it should be put into water acidulated with 10 grammes of vinegar to the litre and remain immersed in this liquid for about an hour and a quarter. All vegetables ordinarily eaten uncooked may be subjected without any inconvenience to the same process.

Correspondence.

"Audi alteram partem."

PROFESSOR EDWARD PARKES ON A SPIRIT RATION.

To the Editor of THE LANCET.

SIR,—In a discussion on the issue of a rum ration to our soldiers I have been expecting to see some reference made to the most important scientific experiments on this subject in the Ashanti Campaign in 1874, which were made by Edward Parkes, F.R.S., to whom the British army is enormously indebted for the improvements he effected in its hygiene. The results of these experiments were published in THE LANCET in August, 1874, and reprinted with introduction and appendices in a small pamphlet entitled "On the Issue of a Spirit Ration during the Ashanti Campaign of 1874" (London: Churchill, 1875). This report is so valuable that one would like to reprint it in its entirety. This being impossible I would like to quote some of his conclusions verbatim.

"It (alcohol) is not a perfectly reliable aid, and requires, when used at all, to be so with a full knowledge of its mode of action (p. viii.). The first effect of alcohol, when given in a moderate dose (for example, what is equal to one fluid ounce of absolute alcohol) is reviving, but this effect is transient. As shown both in the Report and in the first Appendix, the reviving effect goes off after, at the utmost, two and a half miles of additional march, and sometimes much before this; then the previous languor and sense of exhaustion not only return, but are sometimes more intense, and if alcohol is again resorted to its effects now are less satisfactory. Its reviving power is usually not so marked, and its peculiar anaesthetic and narcotising influence can only be distinctly traced. The men feel heavy, dull, disinclined to march, and are less willing and cheerful. It is clear, then, that alcohol is not a very trustworthy aid; for supposing a commanding officer, having marched twelve or fourteen miles, and desiring to cover ten more miles, finds his men weary, and, not being able to halt and feed them, orders an issue of spirits of an amount sufficient to revive but not to depress. The first effect will be good, but in less than an hour his men will be as weary as before, or probably more so. If he then reissues the spirit within so short a period of time it is certain that in the case of many men, perhaps the majority, the marching power will be lessened (p. viii.). Even the reviving power of the first issue is not always so considerable as might be supposed, and, indeed, I have been surprised to find how little good effect it has sometimes produced. It appears to me, therefore, that spirits, as an issue, should be kept for emergencies, as when after great fatigue a sudden but short exertion is required, or, when a march being ended, there is great depression and failure of the heart's action, such as occurs when men have been thoroughly wetted during an exhausting march. To give strength to the men during the march, when the usual food cannot be taken, the meat extracts and coffee are both better than spirits (p. ix.). The first Appendix shows how unanimous the soldiers who were experimented upon were in assigning a great superiority in reviving and sustaining power to the meat extract over the spirit. The meat extract can also be repeated over and over again without injury, indeed with benefit. Coffee, again, is also very reviving during fatigue, and has the great advantage of quenching thirst much better than the meat extract, but it requires to be well made and to be palatable, which is not always easy to ensure in forced marches (p. x.)."

In his report Professor Parkes distinguishes sharply between *facts* and *opinions* (p. 28). The chief facts are:—

"1. Entire abstinence from alcohol did not make the men more sickly as a whole or more disposed to malarious fever (p. 28). 2. The marching powers of teetotallers were good. The evidence is against the usefulness of rum during marching. 3. The reviving effect of the rum when given at the

end of the day was strongly spoken to (p. 31). Under exhaustion after great exertion alcohol will quicken the heart and act for a time as a restorative, though it may be hurtful or not useful during the actual period of exertion. The general feeling of warmth caused by alcohol and the temporary strengthening of the heart's action were also, no doubt, succeeded by a slight anæsthetic effect, making the sleep rather more profound. 4. The evidence of one or two of the men is that they marched better when rum had been issued on the previous evening. 5. Some of the evidence indicated the greater power of digestion given by the rum and the increased appetite given by somewhat changing the monotony of the food. Such appear to be the main facts brought out by the evidence (p. 32)."

The opinions of the different witnesses were rather various, and therefore I may perhaps state shortly my own opinion founded on the facts. The use of alcohol in the body is like the use of a bill in commerce which may enable a merchant to tide over a financial difficulty by enabling him to make calls upon his capital in order to meet his present wants. If the call is simply temporary the bill may tide him over a crisis and will thus be most useful, but if his reserves are insufficient it will only hasten bankruptcy. In like manner alcohol enables a man to call on his reserves of strength and may enable him to make a spurt which he could not do without it. But if the exertion is to be long continued it simply accelerates exhaustion. After the exertion is over and the man is too tired to eat, the alcohol will help to call up his reserve strength and enable him to eat and digest better than he could without it, so that the increased assimilation of the evening meal and better sleep following it may enable him to march better next day. During exposure to cold in a healthy man the cutaneous blood-vessels contract and the blood is thus prevented from circulating over the surface and becoming cooled by the external cold. This protective mechanism sometimes continues to act after the necessity for it has ceased, and not only keeps the surface cold after the person has entered a warm room, but prevents the blood from conveying the external warmth to the internal organs. Alcohol dilates the cutaneous vessels, and by allowing warm blood from the interior of the body to circulate over the surface it causes a pleasant feeling of warmth when the external air is cold, and may also produce coolness by evaporation of sweat from the skin during exposure to heat. If the exposure to cold is short and slight, no harm may be done, but if the exposure is long continued or the external cold is great the skin is warmed at the expense of the vital organs and death results. For this reason the men who cut down timber in the Canadian forests in winter, knowing that intoxication means death, remove temptation by prohibiting spirits entirely, or as Sir Anthony Hope (quoted by Parkes, p. 15) says, "It is an inexorable rule that all drinks found in the camp are destroyed." Meat extracts and coffee when they can be obtained are not liable to the same objections as alcohol, and Parkes has carefully drawn attention to their useful qualities.

In trying to sum up one is obliged to return to Parkes's statement (p. viii.) that alcohol "requires when used at all to be so with a full knowledge of its mode of action." Such a knowledge as this can hardly be possessed by combatant officers, but it may and should be possessed by medical officers, and therefore a spirit ration to soldiers should not be issued haphazard, but only on the order of a medical officer.

I am, Sir, yours faithfully,

New Cavendish-street, W., March 1st. LAUDER BRUNTON.

SANITATION IN INDIA.

To the Editor of THE LANCET.

SIR,—In a resolution dated May 23rd, 1912, the Government of India laid down that certain additional appointments of Deputy Sanitary Commissioners and first-class health officers were to be created. It was required: (1) that candidates should possess registrable medical qualifications and British Diplomas in Public Health; (2) that no officer is appointed who is not an accepted candidate for the Sanitary Department. Indians were held eligible. In regard to first-class health officers, it was stated "the necessity for a British diploma will, however, be only temporary, as the Government of India trust that it may be possible to remove the second restriction so soon as arrangements can be made in India, which will enable Indians to be trained in this country (India) to become health officers of the first class." No similar relaxation is provided for in respect to Deputy Sanitary Commissioners. Although much water has flowed beneath the Sara Bridge since May, 1912, the "arrangements" for supersession of British diplomas are not yet in working order. Consequently several intending Indian candidates have undergone the labour and expense of obtaining in Great Britain the necessary qualifications.

An intelligent Indian who had studied for the D.P.H. at King's College recently presented himself before a Sanitary Commissioner in India as a candidate for the Sanitary Department. In reference to his qualifications he was informed by this official that he has "no faith in the D.P.H. diploma—that it is all cramming," and that if he desired to enter the Sanitary Department he must be prepared to work his way up "from the very bottom rung of the ladder." In describing the hopelessness of his position to Professor Hewlett this candidate adds as to the prospects of his late co-students at King's College, "not one of our set has succeeded in obtaining any suitable job."

We have no wish to suggest that because a man has gone to the expense and trouble of securing special qualifications he must necessarily receive an appointment, or that, for reasons unknown to us, a particular man may not be an undesirable candidate; but it does seem to us uncalled for that the rejected and dejected individual should be informed that the British diploma he has gained at infinite pains is of no practical value. This verdict is as paradoxical as it is, in this instance, unjust; as, whilst first-class officers are invited to look forward, in the resolution of the Government of India, to being provided with local qualifications in public health when arrangements are complete, officers of superior status in the Sanitary Department (Deputy Sanitary Commissioners) are not to be so exempt, which seems an extraordinary requirement if the British diploma be of so little value.

The effect of a statement of this description upon Indian minds from an official responsible for making nominations for sanitary appointments cannot be otherwise than to cause the abandonment of seeking sanitary teaching in this country. In our opinion this cannot be to the advantage of "sanitation in India." Whilst applied hygiene in the tropics has much of the nature of a specialty, it can but treat of modifications of those principles of hygiene of universal application with which education for public health diplomas concerns itself. Thus, though doubtless India has numerous suitable officers to teach hygiene, for many years to come, in the presence of incomplete sanitary

organisation and but few sanitary works, "cramming" as to applied hygiene, of which British educational methods are held to be guilty, must become literally the method pursued in that country, for the simple reason that under existing conditions, whilst it is always possible to demonstrate to a class how matters should not be, it is rarely possible to show by practical illustration how they should be. As Indian candidates have from infancy had intimate knowledge of Indian conditions, they can when in Europe safely dispense with illustrations of the former in favour of practical illustrations of the latter. It is, therefore, in our opinion, distinctly desirable that the Indian candidate for important sanitary appointments should regard training in Great Britain as the foundation of his career. That in India thereafter he might be subjected with advantage to post-graduate lectures on certain subjects is self-evident.

So far as results are concerned, it would appear that the Government of India having issued its resolution of nearly three years back has rested content. Granted that this inaction is due to the fact that interference with local governments was not desired, these might at least have been invited to draw up rules for general information, within their own areas, as to how and when the selection of candidates would be made. In the absence of such specific statement in each province Indians have been induced to risk time and money by proceeding to this country, and are liable to be told on their return that the "scrap of paper" they bear back with them is worthless. This is the case also with candidates for second-class health officerships, whose "main qualifications" were defined, in the resolution above quoted, "as a good general education supplemented by a course of training in public health approved by the local government." In the light of this resolution several Indians came to this country for training without guidance as to subjects requisite or the class of institution they should apply to; and now we find that certain local governments desire that second-class health officers shall in the first place acquire a medical education. Obviously it has not sufficed for the Government of India to have passed a resolution three years ago; the progress of the policy then pronounced demanded subsequent careful fostering or modification.—We are, Sir, yours faithfully,

LOUIS DANIEL BEAUPERTHUY AND MOSQUITO-BORNE DISEASES.

To the Editor of THE LANCET.

SIR,—In my Huxley lecture published in THE LANCET of Nov. 7th, 1914, I gave a short review of some of the work upon which our modern theory of mosquito-borne diseases has been based. My lecture was reviewed by Dr. Andrew Balfour in the *Tropical Diseases Bulletin*, 1915, Vol. V., No. 1, p. 34. He says: "In this connexion the name of Beauperthuy might have been given honourable mention, for his work was at least as meritorious as that of King, and he wrote

long before the latter." I generally try to be very scrupulous as to the work of those who can claim to have any genuine share in scientific discovery, and I did not mention Beauperthuy in that lecture because I did not think that his contributions to the subject of insect-borne diseases were of sufficient importance. I have not read Beauperthuy's original papers because they are not, I believe, accessible in this country, but I studied numerous abstracts from them published by Sir Rubert Boyce in his "Mosquito or Man," and could scarcely share the very enthusiastic appreciation of his work given by Boyce—who was himself an enthusiast, but one who did not possess much critical tendency and who had only lately commenced the study of this subject. I gave an abstract of Beauperthuy's work in my "Prevention of Malaria" (first edition, 1910, p. 15).

The mosquito theory of malaria appears to have originated with the Romans, and was certainly in the mind of Lancisi in 1717, while the idea was so much in the public mind that there was an ordinance of Freetown, Sierra Leone, dated 1812, in which the inhabitants were enjoined to keep their plots in good condition in order to prevent the formation of "stagnant pools which generate disease and mosquitoes over the town." Beauperthuy (1853) appears merely to have repeated these old speculations and to have extended them to a kind of general hypothesis that many diseases are due to the biting of insects. But he does not seem to have thought that the insects carry the germ from man to man, but rather to have believed that they poison human beings by their secretions as snakes do, quite another hypothesis. He definitely says that mosquitoes introduce "a poison which has properties akin to that of snake venom," and thinks that "the expression Winged Snakes employed by Herodotus is peculiarly applicable to the mosquito, and the result of its bite on the human organism." Now such a hypothesis is discredited at once if we remember that persons continue to suffer from fever long after they leave the regions where they are acquired. One might as well imagine that a person continues to suffer from snake-bite years after he has been bitten. Moreover, I doubt whether Beauperthuy ever supported his speculations by careful observation and experiment, and indeed I thought, though I am not very sure of this, that he had scarcely studied sufficiently such a simple thing as a mosquito's proboscis. What may be called scientific speculators of this kind are quite numerous. They love to bring out a number of hypotheses which they state as dogmas and seldom support with sufficient proof, and I think it is a mistake to credit such with a leading share in discoveries which may subsequently be effected by careful thought and experiment working hand in hand. This is especially the case when the speculator not only gives little evidence, but uses very poor arguments, as I think Beauperthuy did. I do not at all agree with Dr. Balfour that Beauperthuy's talk was as meritorious as the able paper by Dr. A. F. A. King (1883) on the possible carriage of malaria by mosquitoes. Dr. King's article, which I possess, is a genuine scientific contribution, in which he marshals no less than nineteen reasons in favour of his hypothesis. The work of both these theorists was forgotten when the actual researches which established the relations of insects to disease were commenced and carried out.

As, however, I have not read Beauperthuy's original papers, I have asked Dr. Harald Seidelin, of this

school, who has read them, to give me his opinion, and beg to attach his reply herewith. As the *Bulletin of Tropical Diseases* is scarcely a suitable place for discussions of this nature, which are, however, of much interest, I hope that you, Sir, can find space for both these letters.

Yours faithfully,

RONALD ROSS.

Liverpool School of Tropical Medicine, Feb. 26th, 1915.

[ENCLOSURE.]

Feb. 26th, 1915.

DEAR SIR RONALD,—At your request I write you giving my opinion on the subject of Beauperthuy's announcement of the mosquito transmission of disease.

The importance of Beauperthuy's work has been considerably over-rated. This was pointed out some years ago by Guiteras (1910). Unfortunately the publications of Beauperthuy are not easily accessible, a circumstance which probably contributes to make his life and work somewhat legendary. Quotations are given by Agramonte (1908), who in exaggerated terms drew attention to the importance of Beauperthuy, and by Boyce (1909). In the latter work especially readers who have no access to Beauperthuy's own writings will find considerable information. Also Sir Rubert Boyce spoke highly of Beauperthuy as a man and of his work, but in the latter respect I am not able to follow him. Like Sir Rubert Boyce, I am indebted to Dr. de Verteuil, Port of Spain, Trinidad, for the loan of the posthumous collection of Beauperthuy's scientific papers (1891). Being particularly interested in yellow fever work, I paid special attention to the sections dealing with this subject. The whole book consists of loosely connected, or completely disconnected aphorisms. The idea of miasms is, with good arguments, shown to be erroneous and unfounded, but just as phantastic ideas about the transmission are set forward—ideas which are often changed from one page to another. Plague, cholera, and most other infectious diseases, including (according to one statement on p. 152) tuberculosis, are said to be transmitted by means of ascaridæ or "insects." The transmission is not supposed to take place from one individual to another, but the insect is believed to absorb some poisonous substance from decomposed organic material.

The section dealing with yellow fever contains (pp. 131-138) a description of the disease and its epidemiology; then follows (p. 138) a description of the mechanism of the bites of "les tipules," apparently without any connexion with the preceding paragraphs, as is so common in the book.

With regard to the transmitting insects Beauperthuy says: "Les agents de cette infection présentent un grand nombre de variétés qui ne sont pas nuisibles au même degré. La variété *zancudo bobo*, à pattes rayées de blanc, est de quelque sorte l'espèce domestique. Elle est la plus commune et sa piqure est inoffensive comparativement à celle des autres espèces." Agramonte asserts that this "zancudo bobo" is the *Stegomyia fasciata*, but Guiteras takes a different view. Personally, I think that the reader's first impression would be that Beauperthuy refers to *S. fasciata*, but Guiteras supports his emphatic denial with very good reasons. He points out that "bobo" means "silly" or "dull," adjectives which certainly no acute observer would make use of in order to characterise the very active *S. fasciata*. He also states definitely that the term "mosquito bobo" is applied (in Cuba presumably) to *Culex sollicitans*, to which mosquito he believes that Beauperthuy was referring. This is a detail, but one not without importance. Another question, of no less importance, is whether Beauperthuy really intended to say that this particular "zancudo bobo" carried the yellow fever infection, or to point out its comparative innocuousness in this respect. Again, we find that Agramonte takes the first view, which is also adopted by Boyce; Guiteras the second. On reading the book, I received exactly the same impression as Guiteras, who says that Beauperthuy "singles out this particular mosquito precisely to say that it is not the producer of yellow and malarial fevers." I must, however, admit that there is a possibility of interpreting his words otherwise. It depends largely on the translation of the word "inoffensive"; if this word is translated "harmful," Guiteras is obviously right, but if the translation "painful" is adopted, then Agramonte's opinion is not wholly untenable. This is perhaps the key to the whole discussion; some of Beauperthuy's statements are

so vague that almost any interpretation may be put forward without too great a risk of being refuted as absurd. It is certainly remarkable that Beauperthuy should harbour and express such ideas concerning insect transmission of diseases. But the value of these ideas is greatly curtailed when it is remembered that they did not include the transmission from man to man, and, more important still, that he was discussing many kinds of fever which we now know to be transmitted in other ways. His words were prophecies, and they happened to come true in some cases, but it is almost equally important that they proved failures in other cases.

The question of the importance of Beauperthuy's work is of particular interest because praise of Beauperthuy has, on some occasions, been used as a means of belittling the work of Finlay. This was the reason which prompted Guiteras to write the letter referred to above. Also to me it appears absolutely incomprehensible how anybody can give anything like equal importance to the work of Beauperthuy and to that of Finlay, as is done by Agramonte, and also in an editorial note in THE LANCET in connexion with Guiteras's letter. Finlay indicated the transmission from man to man, indicated *S. fasciata* as transmitting insect, and indicated the essentials of a rational yellow fever prophylaxis, supporting his ideas by careful observations, logical reasoning, and valuable, if not conclusive, experiments. Beauperthuy did absolutely nothing which can be compared with all this.

Yours sincerely,

HAROLD SEIDELIN.

THE HUNTERIAN ORATION.

To the Editor of THE LANCET.

SIR,—There is rather an important slip in my Hunterian Oration, published in your issue of Feb. 27th, which I should like to correct. It occurs in the last line of the last paragraph on p. 425, which runs thus, "but still no growth has occurred." The word "no" should be omitted—there was copious growth.

I am, Sir, yours faithfully,

W. WATSON CHEYNE.

Royal Naval Hospital, Chatham, Feb. 28th, 1915.

THE PREVENTION OF INSANITY.

To the Editor of THE LANCET.

SIR,—At this time of national upheaval, when most social efforts for the benefit of civilians are receiving but scant notice from the public, there is one movement to which it behoves both the profession and others to give immediate attention. This is especially urgent because there are at the moment before Parliament Bills purporting to deal with the question. I refer to the effort to lessen the present steady increase of insanity in the country. The multiplication of large asylums for certified patients will not do this. Cannot something be done in the way of prevention? A large number of cases of insanity are the outcome of longer or shorter periods of mental strain due to anxiety, shock, overwork, insufficient means, ill-health, uncongenial surroundings, and trouble of many other kinds. If available facilities existed for relieving such patients from the pressure of their injurious environment, and for a time giving them rest and treatment under medical care, a final breakdown might in a large number of cases be avoided. For the lower middle classes and the poor, however, the possibility of obtaining such treatment does not exist outside the walls of certified asylums. Yet physicians of experience

are well aware that many cases of mental affection are absolutely recoverable without the painful experience of certification or exposure to the trials of an asylum, and that from fear of these both patients and their friends tend to postpone treatment till a worse result is inevitable.

There ought, therefore, to exist places (not run for profit) to which the ordinary practitioner could advise these patients to go, just as they would enter any other hospital or convalescent home, and where, in a normal atmosphere, they would receive the treatment, control, and encouragement their state requires. These might in some cases be wards of general hospitals, in others separate establishments, but the *sine quâ non* is that they should be entirely unconnected with all idea of lunacy and lunatic asylums. On this account it is obvious that such homes ought not to be under the management of the Board of Control, but rather that of the Local Government Board. This would be a guarantee to patients that they would in no way be confused with the mentally deficient or the certifiably insane. No small element in the preventive usefulness of the homes would consist in the sense of freedom and hope with which they could be entered, as well as the absence of all stigma on those who left them recovered.

I am, Sir, yours faithfully,

HELEN WEBB, M.B.

St. George's-square, S.W., Feb. 27th, 1915.

FOOD-SUPPLY OF THE GERMAN PEOPLE.

To the Editor of THE LANCET.

SIR,—Might I beg you to allow me a statement in regard to your interesting reproduction of Dr. Paul Eltzbacher's pamphlet on Food-supply of the German People in your issue of Feb. 20th. Under "Prohibition of Exports" (p. 392) Dr. Eltzbacher states that "it is much to be regretted that our Government in friendly consideration for Switzerland allowed 2500 wagons of grain to be exported." I have to state the fact that these 2500 wagons of grain refer *not to German grain*, but to *foreign grain in transit* through Germany at the outbreak of the war. The Swiss Government made strenuous and successful efforts to secure this grain, the property of private firms in Switzerland.

I am, Sir, yours faithfully,

Zürich, Feb. 25th, 1915.

THEO. ZANGGER, M.D.

SECURITY OF TENURE FOR MEDICAL OFFICERS OF HEALTH.

To the Editor of THE LANCET.

SIR,—I enclose copy of a letter I have received from the President of the Local Government Board, which you may care to publish.

I am, Sir, yours faithfully,

Gloucester-terrace, Hyde Park,
March 1st, 1915.

PHILIP MAGNUS.

[ENCLOSURE.]

Local Government Board, Whitehall, S.W.,
Feb. 26th, 1915.

DEAR SIR PHILIP MAGNUS,—I have given very careful consideration to the question of the tenure of office of medical officers of health and sanitary inspectors, which the deputation, which you introduced some months ago, brought before my colleagues and myself at the House of Commons.

Without fresh legislation, I could only deal with the case of officers whose appointments are subject to regulations made by the Local Government Board. These regulations at present allow a local authority the option of making

appointments terminable by three months' notice, or making permanent appointments. I am willing to alter these regulations so that, in the case of future appointments of whole-time officers, the officer shall continue to hold office until he is removed by the local authority with the Board's consent, or is removed by the Board.

I am advised that no Order could be issued which would, of itself, transform present temporary appointments into permanent appointments, but I should be quite prepared to suggest to local authorities that all officers holding temporary whole-time appointments should be re-appointed under the new terms.

The question of part-time appointments seems to me to be in a different category, and I am inclined to think that it is desirable that some inquiry should be undertaken into the general question of these appointments before any change is made in regard to the tenure of office of part-time officers. But such an investigation must, I fear, be postponed until more normal times.—Yours sincerely,

(Signed) HERBERT SAMUEL.

OPEN-AIR TREATMENT OF ACUTE SPECIFIC FEVERS.

To the Editor of THE LANCET.

SIR,—I am glad to see the letter of Dr. Philip Boobbyer in THE LANCET of Oct. 3rd, 1914, on this subject. At the Congress on Infant Mortality in 1913 I advocated the treatment of measles on the open-air principle. In the Malay Peninsula measles hardly ever causes a death, though epidemics of the disease occasionally occur. But if measles in the Malay Peninsula is taken into the ordinary hospital and at all crowded death is liable to occur from pneumonia.

In England it is said that notification is of no use for measles because the disease is infectious before diagnosis can be made, but without notification there can be no knowledge of the occurrence of the disease. And I believe that were all cases taken immediately into the open air, put into tents or any kind of structure which would give reasonable shelter from rain or snow, less would be seen of the broncho-pneumonia, and the 10,000 deaths that occur each year in England from this disease would be greatly diminished. I do not advocate the isolation of all contacts; they could be left in their homes, but the immediate transference to the open air of every case as soon as it occurred would, I believe, reduce the death-rate from this disease to a very low point.

I am, Sir, yours faithfully,

Jan. 26th, 1915.

J. TERTIUS CLARKE,
Health Officer, Kinta, Perak.

THE PROPHYLACTIC TREATMENT OF PUERPERAL INFECTION BY DILUTE SULPHURIC ACID.

To the Editor of THE LANCET.

SIR,—The letter of Dr. J. L. Moir in THE LANCET of Jan. 16th as to the use of dilute sulphuric acid as a prophylactic in labour induced me to try it. One case was that of a shoulder presentation in a contracted pelvis requiring considerable manual interference in turning and application of forceps to the after-coming head, together with manual extraction of the placenta due to irregular contraction of the uterus. The only temperature was 99.2° F. on the third and fourth day, when the breasts became distended, otherwise it was quite normal throughout the puerperium. Gloves were used and asepsis, as much as possible in a one-roomed tenement, attempted. Another case was that of hydrocephalus in which morbidity from septicæmia is

recorded as being high, but the temperature was below 99° throughout the puerperium, except when the breasts were full. In this case I should say that the delivery was spontaneous, the child having died some days previously, with the result that the head was quite flaccid, besides which the right parietal was quite membranous—no bone whatever to be felt, but the foetal membranes were much discoloured. Two cases are not much to come to a conclusion about, but I record them for what they are worth.

I am, Sir, yours faithfully,

City-road, E.C., Feb. 27th, 1915.

J. J. UDALE.

EARLY DIAGNOSIS OF CEREBRO-SPINAL MENINGITIS.

To the Editor of THE LANCET.

SIR,—May I suggest that an examination of the blood is of importance in the early diagnosis of this disease, as the latter is, in my opinion, essentially a coccæmia, and in addition to the presence of the diplococcus in the blood a marked polynuclear leucocytosis is present. This view is based upon the examination of 80 cases, with 30 controls, made in 1899.

In a recent lecture by Sir William Osler¹ mention is made of the presence of the germ in the blood.

I am, Sir, yours faithfully,

Colwall, Feb. 28th, 1915.

MARY H. WILLIAMS.

THE SALE OF DANGEROUS SHELL-FISH.

To the Editor of THE LANCET.

SIR,—In regard to the interesting annotation on this subject in your issue of Feb. 27th, it may be pointed out that the Royal Commission on Sewage Disposal and the Fishmongers' Company have rendered excellent service in indicating the directions in which public protection from contaminated shell-fish could be effected.

When numerous representations some time ago were made by local authorities to the Local Government Board to the effect that further powers were required to prevent danger to health from the consumption of shell-fish grown or fattened in polluted waters the matter was referred to the Royal Commission on Sewage Disposal. In their fourth report the Commissioners stated they were satisfied that a considerable number of cases of enteric fever and of other illness were caused by the consumption of shell-fish which had been exposed to sewage contamination, and they made certain recommendations for preventing the sale of polluted shell-fish for human consumption. So far no alterations in the law recommended by the Commission have been made, but last week the Local Government Board, as you reported, issued an order under powers which it possesses as an alternative procedure. In drawing up this order several suggestions made by the Fishmongers' Company have been acted upon. It seems to me that the coöperation of these two bodies has been most valuable and deserves some emphasis. There can be little doubt also that considerable delay in freeing the foreshores, layings, and ponds of pollution is avoided by the "careful examination by a trained person of these places without bacteriological examination of the water or the shell-fish" as recommended by the Commission.

I am, Sir, yours faithfully,

March 1st, 1915.

SANITARIAN.

¹ Brit. Med. Jour., Jan. 30th, 1915.

Obituary.

SAMUEL HERBERT HABERSHON, M.A.,
M.D. CANTAB., F.R.C.P. LOND.,

SENIOR PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

IN Dr. S. H. Habershon, who died on Feb. 26th at the age of 57 years, the medical profession has lost an able and industrious exponent of our art. He had been in ailing health for a considerable time owing to frequent attacks of asthma, succumbing ultimately to sudden cardiac failure. He was the son of the late Dr. S. O. Habershon, formerly senior physician to Guy's Hospital. He received his medical education at Cambridge University and St. Bartholomew's Hospital, where he obtained the Kirkes gold medal and the Lawrence scholarship and gold medal. He also studied for some time in Vienna. He obtained his M.D. degree in 1887, and was made a Fellow of the Royal College of Physicians of London in 1891. He was at one time assistant physician to the Royal Hospital for Diseases of the Chest, and in 1893 was appointed assistant physician to the Brompton Hospital for Consumption and Diseases of the Chest, and full physician in 1902. He devoted himself wholeheartedly to the work of the hospital, and especially during recent years when the introduction of the Insurance Act carried with it "sanatorium benefit." By this time he was senior physician, and much attendance at committees and on deputations to various public bodies fell upon him. On all such occasions he did not spare any energy to acquaint himself with all the details of the movement, especially as it affected the Brompton Hospital. His experience and knowledge of the subject were fully appreciated by his colleagues, and his absence will be keenly felt. Amongst other appointments he had held the post of physician to the St. Marylebone General Dispensary, and he was one of the physicians to the Star Assurance Society. Although physician to a hospital for diseases of the chest, he had made a special study of diseases of the digestive tract, and his book on "Diseases of the Stomach" showed ample evidence of painstaking study and observation of gastric disorders. He was, it may be remembered, the medical attendant of Gladstone, the famous Premier, of whom he had principal charge during the closing period of his life.

By many friends he will be greatly missed, although during the last few years of his life the constant attacks of asthma prevented him from pursuing such an active life as he would have wished. He married the daughter of the late Richard Davies, M.P., Lord Lieutenant of Anglesey. His three sons, all of whom hold commissions in the army, and his widow survive him.

EDWARD COX SEATON, M.D. LOND.,
F.R.C.P. LOND.,

CONSULTING MEDICAL OFFICER OF HEALTH TO THE SURREY COUNTY COUNCIL.

Dr. E. C. Seaton, who died at his residence in Chelsea on Feb. 20th last, was the son of Dr. Edward Cator Seaton, medical officer to the Privy Council, and successor as medical officer to the Local Government Board to Sir John Simon, with whom he was closely associated.

Dr. Seaton was born in Chelsea in 1847, and received his early education at Tonbridge School. Subsequently he entered at St. Thomas's Hospital as

a medical student, and graduated M.B. with honours at the University of London in 1870, proceeding to the M.D. degree in the following year. After a short period of travel he commenced practice as a physician, and in 1872 was appointed medical officer of health of Nottingham, being the first whole-time officer for that town. This post he held until 1884, when he resigned and returned to London. Soon afterwards he was appointed medical officer of health of Chelsea and public analyst. In 1891 he received the first appointment of medical officer of health to the Surrey County Council, which he held until 1910, when he became consulting medical officer of health to this authority. Thus for over 40 years he was engaged in administrative public health work during a period of greatly increasing developments, actively associating himself with new movements, especially in the introduction of compulsory notification of infectious diseases. In connexion with his work he acted as Special Commissioner for the Home Office and Local Government Board in inquiries into the housing of the working classes, and frequently took a prominent part in the activities of societies engaged in promoting the health of the public. In the Royal Sanitary Institute he was particularly interested, and also in the Society of Medical Officers of Health and in the Epidemiological Society. On councils and at congresses he was always a good representative and speaker. From 1886, the year in which he was elected a Fellow of the Royal College of Physicians of London, to 1908 he was lecturer in public health at St. Thomas's Hospital Medical School, and he held the post of examiner in this subject at the Universities of Oxford, Cambridge, and London, and at the English Conjoint Board. He was also Government representative on the Sanitary Inspectors' Examination Board. As a Government nominee on the Metropolitan Asylums Board he did much useful work, particularly in getting the hospitals of that body opened for the instruction of students. In isolation hospitals he took a special interest, and in the Milroy lectures of the Royal College of Physicians in 1896¹ he dwelt mainly on the proper place of these hospitals in the reduction of infectious diseases. He established a system of isolation hospitals for infectious diseases and for small-pox in Surrey, and made his wide experience the theme of the Chadwick lectures, *Infectious Diseases and their Preventive Treatment*, which he delivered in 1910.

Dr. Seaton was greatly esteemed by all his colleagues, and the help and advice which he gave as county medical officer of health to the junior medical officers in the various districts of the county were much appreciated by them. Always taking his work and position seriously, he gave great care and attention to the arrangement and style of his official reports and indeed to all his writings, aiming at moderate views and conservative progress. In addition to the many reports and publications relating to official matters he was the author of the article on Vaccination in "Quain's Dictionary of Medicine," and collected and edited in 1886 Sir John Simon's *Public Health Reports*.

He married in 1875 the daughter of the late Dr. J. Waggett, who died in 1884, and afterwards, in 1892, married the daughter of the late Mr. John Marshall, F.R.S., P.R.C.S., and President of the General Medical Council, by whom he had one daughter.

W. OSCAR S. MCGOWAN, M.B., CH.B. EDIN.

Dr. W. Oscar S. McGowan, of Tabankulu, Pondoland, Cape Colony, whose death occurred recently from pneumonia at the early age of 31, was the eldest son of Dr. William McGowan, Maghera, Co. Derry. His early education was acquired at Foyle College, Derry, and Royal School, Dungannon. From the latter he proceeded to the University of Edinburgh, where he pursued his medical studies, and graduated M.B. and Ch.B. in 1906. He was house surgeon in the Cardiff and Leicester Infirmaries and then got a similar appointment in the New Somerset Hospital, Capetown, where he remained 12 months. On the recommendation of the Duke of Abercorn, chairman of the British South Africa Company, he obtained an important appointment from the Company near Salisbury, in Southern Rhodesia. Subsequently he was promoted to another appointment near Bulawayo in the service of the same Company, in charge of a native hospital.

In November last he took over a practice with the post of district surgeon attached in Pondoland, Cape Colony, and settled down with good prospects. Owing to his bright and genial temperament he was a universal favourite wherever his lot was cast. He was fond of outdoor sports, especially shooting, and in Rhodesia he had many opportunities of indulging in this pastime, even in the pursuit of big game.

Dr. McGowan was married in Salisbury in May, 1912, to Madlyn, daughter of the late Robert Warren, Cedarville, East Griqualand. His widow and one child survive him.

CHARLES HARPER, L.R.C.P. EDIN., M.R.C.S. ENG., R.N. (RETIRED).

Mr. C. Harper, who died at his residence, Bath-easton, Bath, on Feb. 16th, in his eighty-eighth year, became M.R.C.S. in 1849, and ten years later took the L.R.C.P. of Edinburgh. He entered the Royal Navy as surgeon in 1853, and served with the British Fleet in the Baltic during the Crimean War, and was present at the taking of Fort Bomorzund. Mr. Harper was well known and highly respected in Bath and the district, where he had an extensive practice. He was for 32 years medical officer of health of the Bath rural district council, and was also the first chairman of the Batheaston parish council. He leaves two sons, Brigadier-General G. M. Harper, D.S.O., of the Royal Engineers, who is on active service, and Mr. J. M. Harper, M.R.C.S., of Bath.

LUNACY IN LONDON.—A summary of the annual returns of lunacy presented to the London County Council on March 2nd showed that the number of persons for whom the Council is responsible to find accommodation had increased by 368, 40 per cent. in excess of the increase shown on Jan. 1st, 1914 (262), but considerably less than the average annual increase (458) for the last 25 years. The increase in the total number of lunatics in the county was also greater than last year, being 379 against 308, but here again this year's figure was considerably below the average (514). A satisfactory feature of the returns was the further reduction in the number of criminal cases in the county asylums. The Council had made representations to the Home Office as to the undesirability of this class of patient being sent to county asylums, and recently further accommodation for criminal lunatics had been provided by the State. The total number of patients (pauper, criminal, and private) in the asylums during the year was 20,589, and the number boarded out was 1108. The number of patients privately maintained had been reduced, apparently owing to losses caused by the war and the high cost of living.

¹ THE LANCET, vol. i., 1896, pp. 601, 698.

THE BELGIAN DOCTORS' AND
PHARMACISTS' RELIEF FUND.

THE CENTRAL EXECUTIVE COMMITTEE.

A MEETING of the Central Executive Committee was held on Thursday, Feb. 25th, at the offices of the British Medical Association, when the progress of the Fund announced was very satisfactory. Owing to the favourable terms obtained by Dr. Des Vœux for money left upon deposit with the bank, it was decided to invite those responsible for some of the local funds, now remaining in the hands of their local treasurers, to pay such contributions into the Central Fund at an early date. In this connexion it was reported that the Scottish Committee desired to work in complete coöperation with the English Committee and would appoint representatives on the executive.

Mr. Meredith Townsend, the Master of the Apothecaries' Society, reported that Mr. Samuel Osborn had expressed a willingness to take a selection of the surgical instruments sent in to the society to Belgium for use in certain hospitals behind the fighting line where they were required, and Sir Rickman Godlee said that he would help Mr. Townsend in making the selection, which would be mainly in the direction of cases of operating instruments.

A report was received from the treasurer which showed that the applications for help in money during the past fortnight had not been very numerous. A certain number of registration fees had been paid for Belgian medical men registering on obtaining work to do, and the general ignorance among the Belgian doctors of the English language appeared as the chief difficulty of finding appointments. The working of the clothes bureau at 3, Hyde Park-street, London, W., where Dr. Clément Philippe has kindly provided the necessary accommodation, proceeds successfully. Money was granted by the committee for the further purchase of clothes, especially of undergarments and boots.

MANCHESTER AND DISTRICT.

The total sum received to date is £336 15s. 6d., of which £32 8s. have been contributed by the general public. The committee hope that those medical men who wish to subscribe will send in their contributions at their earliest convenience.

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Ltd. £7200 had passed into the treasurer's hands by Tuesday last, the sum not including the Scottish and Irish and several large local funds.

"SPOTTED FEVER" IN ULSTER.—The Antrim board of guardians have decided to approach the authorities of Purdysburn fever hospital, Belfast, to make provision for cases of cerebro-spinal meningitis (spotted fever), several of which (four) have occurred in their district, two of them being in the military camp at Randalstown. A case is also reported from the Clondeboy camp.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Caxton House, Westminster, on Feb. 17th, Sir Francis H. Champneys being in the chair. A number of midwives were struck off the roll, the following charges amongst others having been brought forward. A patient suffering from puerperal mania, and the midwife having explained that the case was one in which the attendance of a registered medical practitioner was required, she neglected to hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E.19, and medical aid having been sought as aforesaid, she neglected to notify the local supervising authority thereof, as required by Rule E.21 (1). The midwife not being scrupulously clean, as required by Rule E.1; not taking and recording the pulse and temperature of patients, as required by Rule E.13; that when called to a confinement the midwife did not take with her the bag and appliances prescribed by Rule E.2. That with intent to avoid inspection and supervision the midwife abstained from notifying the local supervising authority of her intention to practise as a midwife, as required by Section 10 of the Midwives Act, 1902. The midwife did not wear a clean dress of washable material, as required by Rule E.1. A child being born apparently dead, the midwife neglected to carry out any method of resuscitation, as required by Rule E.14. That being in attendance as a midwife at a confinement, and the child having died before the attendance of a registered medical practitioner, the midwife neglected to notify the local supervising authority thereof, as required by Rule E.21 (1) (b). A midwife, notwithstanding repeated warnings and instruction, persistently neglected to comply with the rules of the Central Midwives Board, and she did not keep her register of cases as required by Rule E.23.

The War.

HONOURABLE MENTION IN ADMIRAL BEATTY'S DESPATCH.

AMONG those officers mentioned in the despatch of Admiral Sir David Beatty referring to the naval action in the North Sea on Jan. 24th is the name of Surgeon-Probationer James Alexander Stirling, R.N.V.R., H.M.S. *Meteor*, on whom the King has conferred the Distinguished Service Cross.

THE CASUALTY LIST.

The casualties among officers in the Expeditionary Force reported since our last issue include the names of Lieutenant E. H. Moore, R.A.M.C., Lieutenant T. M. Davies, R.A.M.C., and Captain S. J. Linzell, R.A.M.C., who have been wounded.

THE BRITISH INTERNMENT CAMPS.

A Swiss correspondent writes: "A report which has been compiled by Professor Edward Naville, a member of the International Committee of the Red Cross Society, and M. Victor van Berchem on the conditions prevailing at the British internment camps should finally silence criticisms upon this subject in the German medical and lay press. The report of these delegates will be published shortly, but the extracts which have been supplied to the Swiss press clearly indicate its tenor.

The delegates, who were given entire freedom of inspection by the War and Foreign Offices, speak in the highest terms of praise of the treatment accorded both to the civil and military prisoners. The food, they state, is excellent; the rooms well-lighted and admirably heated; the sanitary conditions all that could be desired. Although they questioned a considerable number of prisoners they did not hear one single complaint. The Swiss delegates visited the ships upon which a considerable number of Germans are imprisoned, and their impressions were entirely satisfactory. They nevertheless express the view that on the return of warmer weather the prisoners should be transferred to the shore camps. So far as can be gathered from the published summary of their report the arrangements for the spiritual care of the prisoners alone meet with criticism. These arrangements, they state, are altogether insufficient, at one camp the clergyman who ministered to the needs of the Roman Catholic prisoners not knowing one word of German.

Emphasis is laid upon the fact that there are no women or children in the civil internment camps, and the report concludes as follows: "We do not hesitate to state that our impression was very satisfactory. The prisoners—above all, the soldiers—are well treated, and in adopting the principle that their life should entirely resemble that of English soldiers the Government has cut away the ground for any kind of complaint. These prisoners, in fact, could not be better treated. In particular, we heard not a single complaint against the soldiers who guard the prisoners or against a single Englishman with whom these latter had dealings. Nothing is allowed to hurt their feelings as soldiers or as patients. Our conclusion is that neither the German Government nor the families of the prisoners need have any anxiety about those interned in the camps in England."

VOLUNTARY HOSPITALS AND WOUNDED SOLDIERS.

In THE LANCET of Jan. 16th we published a short account of the steps taken by the Council of the British Hospitals Association to coördinate the various conditions under which the voluntary hospitals of Great Britain are receiving wounded soldiers for treatment. After consultation with a number of hospital secretaries the council made an application to the War Office to deal upon the basis of uniform scale of payment with those voluntary hospitals desiring payment for this service. The joint honorary secretaries of the association now announce that a reply has been received from the War Office to the following effect:—

That the general principle adopted as to payment for hospital accommodation for wounded soldiers is that the hospital concerned should take up the question with the general officers of the command or district in which the hospital is situated, with a view to fixing a reasonable rate of payment, having regard to the circumstances of each case. It will be obvious that considerable variation in the rates paid is inevitable in the circumstances, but the Council are of opinion that the system adopted is that best suited to meet the needs of the situation and has, so far as they know, worked satisfactorily hitherto.

In these circumstances the Council of the British Hospitals Association recommend the voluntary hospitals who have not already made arrangements for payment, but who desire payment to be made for these patients, to apply to the local military authorities as suggested by the War Office.

TRENCH FEET.

The following descriptive diary on trench feet, from the pen of an officer suffering from so-called frost-bite, has been forwarded to us by the Director-General, Army Medical Service, Overseas, for publication in THE LANCET:—

Jan. 18th: Put vaseline on my feet, then two pairs of socks and ammunition boots, and marched to trenches, about four miles. Spent quite four hours of the night walking from one trench to another, getting wet frequently up to the knees and once nearly to hips, but did not feel cold all night, as I was all the time on the move.

Jan. 19th: Feet cold occasionally by day. I then stamped them on trench boards. I did not change socks, as the others would have been wet at once. At night same as previous night.

Jan. 20th: Morning and afternoon same as 19th. At about 8 P.M. relieved and went back to a barn where I took off my socks and got rid of mud which was rubbing my heels slightly. After this they were quite comfortable.

Jan. 21st: At 6 P.M. marched back four miles to billets, feet feeling all right, though not comfortable. Soles feeling a little bruised, as still very muddy. Half an hour after I got into billet ankles felt stiff, and in two hours feet were rather painful. I took off socks and found both feet swollen up to above ankle and skin very tight and inflamed. Rubbed on cod liver oil.

Jan. 22nd: Could not put feet to the ground. Soles very tender and ankles felt as if they would turn over if I put weight on them. From now to the 30th my feet were massaged daily by battalion chiropodist with turpentine oil.

Jan. 25th: Most of the swelling had disappeared from ankle and instep, but ball of big toe and under all toes very painful so that I could not put toes on the ground. Also outer edge of foot painful. Both feet always felt like icicles, but were very hot to touch and were actually sweating. Circulation in toes was very slow, began to be very painful at night, even weight of blanket hurt them. By day feet were bandaged in wool and puttees, and I used to keep them up on a chair. When they became very painful it eased them to stand upon my heels for a time.

Jan. 25th to Jan. 31st: Went on as above and could hobble about a room as long as I kept toes off the ground. Ankles now strong again.

Jan. 31st: Sent to No. 2 Clearing Hospital, Bailleul, and down by train that night to Rouen, where I arrived on the evening of Feb. 1st. Keeping them up for this 48 hours (as

I was lying down all the time) made them much more tender, so that when I got to Rouen I could not put right foot to ground at all.

Feb. 1st to 5th: In bed, feet generally rather painful and at times acutely so. Putting them above my head when painful sometimes relieved them. More painful by night. When pain comes on I can hardly bear them lying on the bed. Ball of big toes still very swollen. I cannot yet work my toes. On Feb. 4th ankles swelled again slightly. The ankles feel as if they had been badly wrenched. The pain in the feet is best described as like that experienced by holding snow in one's hands for a long time, combined with the idea of one's feet being in a vice and being squeezed inwards. Occasionally there are shooting rheumatic pains up the legs.

THE LADY HARDINGE HOSPITAL FOR INDIANS.

The Lady Hardinge hospital for sick and wounded Indian soldiers from the front is situated at Brockenhurst in the New Forest, in the grounds of Brockenhurst Park, which have been lent for the purpose by Mrs. Morant. The hospital has been built and organised by the Indian Soldiers' Fund under the auspices of the Order of St. John of Jerusalem in England. The cost of construction was borne by the War Office, which also makes the usual daily payment for each inmate, while the expenses of equipment, maintenance, and administration are being undertaken by the fund. The work of building the hospital was begun in the middle of November last, and the first patients were received on Jan 20th; since that date a considerable number of Indian soldiers have been under treatment.

The hospital stands on high open ground with deep gravel subsoil. It contains 500 beds arranged in 20 wards, each with 25 beds, and 2 isolation wards of 8 beds each. The general wards are grouped on each side of two long parallel corridors, which communicate with each other and with the operating and administration blocks by means of a transverse corridor. Each ward unit is 140 ft. long by 20 ft. wide. It consists of the ward proper (90 ft. in length), and an annexe comprising sisters' rooms, ward kitchen, private ward for one native officer, boot passage, bathroom, and latrine. The operating block consists of clean theatre with sterilising, preparation and anaesthetic rooms, septic theatre and dressing-room, and fully equipped X ray room. The administration block consists of entrance hall, board room, orderly officers' room, dispensary, offices for commandant, registrar, and clerks, clinical laboratory, and well-equipped bathrooms for patients on admission. Separate blocks are set apart for recreation and dining-rooms for patients, self-contained kitchens for Hindu and Mahomedan cookery, admirable supply depôts and store-rooms, disinfection house, and completely detached quarters for medical staff, nursing staff, maids, orderlies, and military guard. The entire hospital is built on the one-storey hut system. The material is galvanised iron lined with plaques of "three-ply" boarding or asbestos composition. Heating is supplied by three steam radiators, and electric light is generated by an oil engine within the grounds, while water is laid on from the Southampton Water Company's supply. The hospital is drained by a water-carriage system leading to two large septic tanks. The medical staff consists of the commandant, Lieutenant-Colonel F. F. Perry, C.I.E., late Principal of Lahore Medical College, assisted by Lieutenant-Colonel C. H. L. Meyer, formerly Professor at the Grant Medical College, who is second in command, and Lieutenant-Colonels W. H. Burke, M. A. T. Collie, J. B. Gibbons, H. Herbert, J. B. Jameson, and H. B. Melville, Major E. O. Thurston, and Lieutenant H. C. G. Semon—all of the Indian Medical Service, past or present. The matron, Miss McCall Anderson, is assisted by 2 assistant matrons, and 16 Hindustani-speaking trained nurses, who have general charge of the nursing and domestic arrangements. Under these there are 60 English orderlies from the St. John Ambulance Brigade, and a menial native staff of some 60 cooks, water-carriers, sweepers, and so on.

On Tuesday last a member of the editorial staff of THE LANCET was given an opportunity of

inspecting the entire institution, under the guidance of Lieutenant-Colonel Perry and Lieutenant-Colonel Meyer, and was much impressed by the manner in which the special and peculiar needs of Indian soldiers have been provided for without interference with ordinary hospital requirements. Every department bears witness to the skill and the special knowledge of native requirements possessed by those responsible for the design and equipment of the institution.

BEHIND THE FRENCH LINES.

The following notes of six interesting cases have been communicated to us by Dr. Machard, surgeon to the Pinchat Hospital, Geneva, acting as surgeon to the French Red Cross Hospital, No. 113, at Chambéry:—

CASE 1.—Skull wound. Fracture of skull, occipital, by contact. Injury inflicted by shrapnel ball, causing seton wound in the soft parts. When the man came under my care he had been suppurating for three weeks at least, and he complained of vertigo, headache, visual disturbances, and stupor. These symptoms were gradually getting worse. I made a valvular incision, exposing an oval fracture with depression of the external table: some splinters of bone were scattered round and the wound exuded pus. I opened up the seat of the fracture with the chisel and gouge, removed the splinters, and curetted the diploë, which was filled with pus. The internal table was intact. The cerebral symptoms rapidly subsided and the suppuration ceased.

CASE 2.—Tangential wound of the skull by rifle bullet. The aperture of entry was on the top of the head in the bi-auricular line, and the aperture of exit in the right mastoid region. He had been trephined in the mastoid region in a hospital in the first line, but there remained left hemiplegia which is improving daily.

CASE 3.—Penetrating wounds of thorax. Bullet entered the thorax on the edge of the eighth rib. No infection, no reaction, rapid recovery. The ball was seen in the radiogram lying in the right hypochondrium.

CASE 4.—Penetrating wound of the left lung. Went in through the left eighth interspace 2 centimetres from the median line. Radioscopy showed the missile in the abdominal cavity near the cæcum. No infection. Signs of pleuro-pneumonia. Recovery in six weeks.

CASE 5.—Bullet entered through the second right costal interspace 9 centimetres from the edge of the sternum. Hæmothorax. The missile could be seen in the radiogram near and just above the right kidney. No infection. Recovery in nine weeks.

CASE 6.—Bullet went in 6 centimetres above the angle of the left scapula. Perforation of the upper lobe of the left lung. The missile was seen in the radiogram in the anterior inferior cul-de-sac of the pleura. Recovery in ten weeks.

Dr. Machard notes: All the patients with infected or stinking wounds on arrival at the hospital were given 10 c.c. of antitetanic serum hypodermically. We lost two patients from tetanus, but this was already present on admission. We only had one case of secondary hæmorrhage from the posterior tibial artery, following a wound of muscle by shell. The bleeding was arrested by forceps, which were left on, as no ligature would hold on account of the gangrenous state of the tissues.

From the Hôtel Mirabeau (Formation Sanitaire), Aix-les-Bains, a special correspondent has sent us some notes of interesting cases which have been under his hands:—

CASE 1.—Extensive cellulitis necessitating 54 inches of incisions. The wounded man, 26 years of age, was a motor-cycle messenger. He had delivered his message on Sept. 5th and was lolling on the grass when he heard a shell coming. Experience enables one to know whereabouts a given shell will fall, and as he estimated that it would fall in his immediate vicinity he jumped to the nearest wall with his

hands before his face. The shell struck the wall and exploded, the fragments inflicting numerous small wounds all over the head, smashed both wrists, and ploughed up both thighs. He did not think he was seriously injured, and had his wounds dressed at the nearest *poste de secours*, 100 yards away. There he remained until 6 o'clock the next morning when he was conveyed to the ambulance. There he passed the day, and at 8 A.M. on the second day he was placed in a cattle truck. The train remained all day in the siding and did not start until 10 P.M. It took a day and a half to reach its destination, during which period the patient had had no medical attention and very little food. He was in a pitiable plight on arrival, exhausted from loss of blood and lack of suitable food. He was found to be suffering from septic cellulitis especially affecting the right lower extremity. The pus burrowed right up into Scarpa's triangle and down past the knee into the ankle. The sinuses passed deeply into the thigh and between the muscle bundles, and ultimately the fascia lata as a whole sloughed and came away in ribands. The pus was quite blue and was horribly offensive as well as extremely copious. Fresh incisions had to be made almost daily to combat the tendency to burrow, the wounds being dressed with iodoform-glycerine (10 per cent.). The total length of the incisions amounted to something like 54 inches. The wrists also became septic and had to be freely incised. The patient was absolutely helpless for upwards of three months. He had to be dressed daily, and for some weeks each dressing had to be done under chloroform so great was his suffering. He was lucky enough to be in the hands of an English nurse (I give her name, Nurse Green), who devoted herself to the care of this long-suffering man, and to her assiduity in great measure his ultimate recovery is due. His temperature during the first few weeks was high, averaging 39° C. He was given large, repeated, intravenous injections of electrargol to combat the infection. It is now four months since he received the injury and he is beginning to hobble round on crutches. It is anticipated that he will regain almost perfect functional use of his limbs.

CASE 2.—Extensive suppurative cellulitis with septic arthritis of knee. Artilleryman. Sustained shell wound of knee and lower end of thigh also on Sept. 5th. He was three and a half days on the journey to the auxiliary hospital. The wounds were already infected and he developed extensive cellulitis necessitating some 52 inches of incisions. Suppuration was profuse, the pus being horribly offensive and light blue in colour. Temperature at or about 40° C. for three weeks. Then septic arthritis of the knee occurred and the joint was opened up, irrigated (iodine water) and drained. Later on he was found to have a large abscess of the calf which was also deeply incised. Meanwhile, in spite of every care, an extensive bed sore formed which gave a great deal of trouble. It finally yielded to a hammock mattress. The patient was a robust, finely built man, and this stood him in good stead, but he became dreadfully emaciated. In this case, too, large repeated injections of electrargol were given to combat the septicæmic condition, with apparent benefit, the temperature, in spite of an immediate rise, always falling after an injection for several hours. It was not until after the expiration of four months that the patient began to be able to get about. The knee is stiff, but there is promise of restoration of movement.

From these cases it is possible to judge of the admirable recoveries that are being made from severe, extensive, and very dangerous injuries, while we get a glimpse of the appalling horrors of those early days of the war, before the transport and care of the wounded could possibly be provided for.

BRITISH RED CROSS SOCIETY.—The summary of the work for the week ending Feb. 27th shows that the society and the Order of St. John of Jerusalem have been persistently busy on behalf of the sick and wounded. At the Netley Red Cross Hospital a total of 388 patients are being treated, amongst whom are a small number of Indian and Belgian troops. The Canadian Red Cross Branch has contributed to the joint funds over \$100,000 to date in addition to large supplies of hospital comforts. The King of Portugal has presented the convalescent home

for British officers at Brighton, which is now opened and which will be personally supervised by His Majesty. Other convalescent homes for officers have been opened at Bath, at the Chateau de Thorenc at Cannes, and at Parkstone, near Bournemouth. Queen Alexandra has presented portraits of herself and King Edward for placing in the King George Hospital, London, and a portrait of herself, which is now placed in the sick bay of the *Queen Alexandra* hospital ship.

KING GEORGE HOSPITAL.—The names of the consulting and visiting medical and surgical staffs of the new King George Hospital have already appeared in this column. The staffs of the various special departments have now been completed.

Department for Diseases of the Throat, Nose, and Ear.—Sir StClair Thomson, Dr. Dundas Grant, Mr. Herbert Tilley, and Mr. Arthur Cheate.

Ophthalmic Department.—Sir Anderson Critchett, Sir William J. Collins, Mr. Ernest Clarke, and Mr. William Lang.

X Ray Department.—Dr. W. Ironside Bruce, Dr. Stanley Melville, and Dr. G. Harrison Orton.

Anæsthetics.—Sir Frederic Hewitt, Dr. G. A. H. Barton, Dr. H. Whitelaw Bourns, Mr. C. C. Braine, Dr. Dudley Buxton, Mr. J. H. Chaldecott, Mr. Herbert Charles, Mr. Richard Gill, Mr. Harvey Hilliard, Mr. R. W. Lloyd, Dr. C. J. Loosely, Dr. Harold Low, Dr. V. B. Orr, Mr. H. M. Page, Dr. Hugh R. Phillips, Dr. Llewellyn Powell, Dr. W. E. Robinson, Mr. George Rowell, Dr. Francis E. Shipway, Mr. Hedley C. Visick, and the Hon. Sir John McCall.

Pathological and Bacteriological Department.—The governing body of the Lister Institute have placed the services of Dr. J. C. G. Ledingham, Dr. W. J. Penfold, and Dr. P. H. S. Hartley at the disposal of the authorities for the bacteriological and pathological services of the new hospital. Fully equipped pathological laboratories, post-mortem rooms, &c., are being arranged for in the adaptation of the new Stationery Office. Dr. Ledingham will be in charge and the bulk of the work will be carried out at the hospital. The Lister Institute will, however, serve as a base for the preparation of culture media, &c., and the advantages of its laboratories will be available for observations requiring more extensive equipment than will exist at the hospital.

Dental Department.—The dental surgeons to the new hospital are as follows: Mr. F. W. Barrett, Mr. W. A. Maggs, Mr. Morton Smale, Mr. Sidney Spokes, Mr. Arthur Underwood, and Mr. C. E. Wallis.

The establishment and equipment of a hospital of five floors of an acre and a half each, with beds for 1650 sick and wounded soldiers—to say nothing of the resident staff—is, of course, a great undertaking. It is being carried out by a small committee consisting of Sir Frederick Treves, Sir Rowland Bailey, and Mr. Edmund Owen, in consultation with the members of the visiting staff. Most of the contracts for surgical apparatus and instruments have already been placed. Each of the six operating theatres will have a working set of instruments, and in addition there will be a central store from which instruments for special operations will be supplied on demand.

2ND WESTERN GENERAL HOSPITAL.—At the commencement of the war the general impression of Manchester citizens was that it seemed absurd to establish a military hospital in the city with 520 beds so far away from the fighting line, and very few could have foreseen or even believed that Manchester would have become one of the chief centres of life and energy in the care of our sick and wounded soldiers, or that the original 520 beds established in buildings erected for other purposes than hospitals would have expanded within four months into a central hospital of 543 beds, and auxiliary, civil and private hospitals, 120 in number, providing 3683 beds, making a grand total of 4526 beds available for the Embarkation General at Southampton to evacuate the hospital ships into. Manchester has indeed risen to the occasion in this matter as it has proved successful in raising new battalions and recruits. The labour entailed in organising and conducting such a work has been carried out in what Lancashire likes to regard as "a true Lancashire spirit," which has enabled all to work together with regularity, energy, and enthusiasm. The original trained nucleus of 3 officers and 43 rank and file was increased on enlistment by 66 men, and on recent expansion by 68 more. Many of these had seen previous service

in the Regular and Territorial Royal Army Medical Corps, and others were expert clerks in civil life, for the clerical work requires a staff of 15 men, working many hours a day—often far into the night. The correspondence amounts to some hundreds of letters a day.

The arrival of a hospital train is a frequent event and each train brings 100 to 250 soldiers in a little over seven hours' running from Southampton. Each train is made up of wards fitted up with 20 cots in each coach in two tiers running the length of the train on either side, and coaches with compartments at either end for sitting-up cases. The train is in charge of an officer of the Royal Army Medical Corps, with 2 nursing sisters and 10 non-commissioned officers and men, who attend to dressings and emergencies en route. There is a small operating theatre, close to which is a dispensary and an office where the list of men carried is made out, as well as a kitchen where meals are cooked for the journey, and a saloon for the staff to live in.

The greatest pressure was experienced at the hospital on Oct. 31st and Nov. 1st, when a sudden expansion of the hospital was called for at a time when all but 150 beds were occupied. In the middle of the night a telephone call from Southampton revealed the fact that there were 7000 wounded at Southampton without sufficient beds to receive them. The General begged for 800 beds, and these were promised if 24 hours were allowed to arrange for them. In less than three hours 628 beds were promised in civil and private hospitals, and the remainder were provided a few hours later by taking over a new school building with the help of the contractors who had equipped the hospital at the commencement. In six trains arriving during two successive nights and with evacuating all day from the main hospitals no less than 823 sick and wounded were admitted in 26 hours to the 2nd Western General Hospital, and there were 90 empty beds to spare. This could not have been accomplished without the assistance of the British Red Cross Society and their splendidly organised fleet of motor transports, consisting of 36 ambulances and 170 motor-cars, in addition to 10 ambulances generously offered and efficiently handled by the Manchester police, who have turned out at all hours for a train call. It would be difficult to find a more suitable detraining station than Mayfield (adjoining London Road Station), which the London and North-Western Railway Company reserve for this service to the exclusion of the public. It cannot be overlooked and has a long platform with a wide roadway the whole length of it. Eighteen ambulances and 30 cars in single file can be accommodated so that the whole train may be evacuated at once. The command of the station is under the charge of the registrar of the hospital, who is assisted by a staff of 4 officers and 24 men, and frequent practice has enabled the men to work quietly and rhythmically in taking out the wounded, so that the time occupied has been reduced to a minimum, the average for a train containing 150 men, including 50 cot cases, being 18-20 minutes from start to finish.

The nature of the cases has altered somewhat. At first all but 5 per cent. were wounded and many severely, but since the wintry weather began about 33 per cent. of sick have been included in each convoy. Several hundred cases of frost-bitten feet have been received, as many as 300 arriving in three train loads. Very few deaths have occurred. The total amounts to 45, of which 11 have been from tetanus. Again, of these 7 were Belgian soldiers who had not received the injection of antitetanic serum that British soldiers receive immediately after being wounded. Only 8 cases of enteric fever have occurred, of which 2 have died. None of the cases had been inoculated. Of 8204 patients, there were 1272 Belgian officers and men and 33 German wounded prisoners. The operations performed in the hospital total 739, and examinations by means of X rays on over 1000 patients. The hospital has received very many gifts from all classes and societies, and the smooth working is in a large measure due to the unfailing readiness of every member of the community to do all in their power to help the brave fellows back to health.

ABERDEEN UNIVERSITY AND THE WAR.—At a meeting of the Aberdeen University Senatus held on Feb. 23rd Principal George Adam Smith reported that in addition to the 767 names contained in the provisional list of Nov. 30th of members of the University who were serving on naval and military service, about 239 names had been

communicated to him of members of the University who had received commissions or who had enlisted. The total number of graduates, alumni, and students on military service or under training was now over 1000, and in addition 15 members of the teaching staff were also serving with the colours. It was decided that owing to the exceptional circumstances prevailing no honorary degrees should be conferred at the forthcoming spring graduation.

VACANCIES FOR MEDICAL OFFICERS.—We are asked to state that there are vacancies for two medical officers in the 2nd Line Welsh Border Mounted Brigade Field Ambulance. Pay and allowances as in the Regular army, also a grant for outfit and camp kit. Further particulars can be obtained on application to Major D. C. Leyland Orton, R.A.M.C. (officer commanding), Thomas-street, Chester.—There are also several vacancies for suitable, qualified, medical officers in the 1st Welsh Border Mounted Brigade Field Ambulance. Applications should be made to Lieutenant-Colonel A. G. Hamilton, R.A.M.C. (T.), Officer Commanding, 30, Station-road, Beccles, East Suffolk.—Colonel Morgan asks us to state that a number of Welsh medical men are required to take up temporary commissions in the Royal Army Medical Corps for duty with the field ambulances and regimental units of the Welsh Army Corps. Applications should be made to the A.D.M.S., 43rd Welsh Division, Prestatyn, North Wales, stating age and qualifications, and any previous experience of military medical work.

THE MILITARY SERVICE DE SANTÉ.—Our Paris correspondent writes:—"The direction of the Service de Santé has organised in every district of the war area special services of neurology, psychotherapy, ophthalmology, otorhinolaryngology, maxillo-facial prosthesis, orthopaedics, urology, and psychiatry. For each specialty in each district there has been established a central service, with secondary services so situated in different towns that the soldiers may easily be evacuated to them. At the head of each of these organisations has been stationed a district médecin chef, who treats the patients and the wounded despatched from the front to the central service, supervises the hospital establishments of the district, and picks out the sick and wounded suitable for treatment by the special service, taking them in at the central service or sending them on for treatment at secondary centres. He also receives the scientific and practical returns of the work of the various special centres in his district. Each month he makes a résumé of reports that seem of special interest, adding to them the results of his own personal practice for communication to the direction of the Service de Santé and to the chiefs of the organisations of the corresponding specialties in other districts. The exchange of these communications is bringing about useful modifications in technique and in the *modus operandi* of the services."

ROYAL PORTSMOUTH HOSPITAL AND THE WAR.—The annual report and balance sheet for 1914 of the above hospital was presented to a meeting of subscribers held in the Town Hall, Portsmouth, on Feb. 26th. It shows that the number of civilian in-patients was 2462, and military 206. Two wards were placed at the disposal of the military authorities for the reception of wounded soldiers in November. The daily average number of beds occupied was 148 and the average cost per bed occupied was £61 17s. 10d. The expenditure amounted to £10,144 and ordinary income to £7192, leaving a deficit of £2952. Legacies amounted to only £220. With the desire not to compete with the war funds the usual Hospital Saturday collections were not undertaken, and increased cost of provisions and medical and surgical requisites have aggravated the deficit. Owing to a powerful appeal of the *Portsmouth Evening News* the sum of £2224 was subscribed for the purchase of radium. All the honorary staff have been serving under the Crown in various directions associated with the war, and have in consequence not been able to give so much time as usual to their duties at the hospital. The resident staff have met the extra demands thrown upon them cheerfully and skilfully.

WIND CONTUSIONS.—M. Sencert reports to the Société de Chirurgie the case of a man who was killed by being less than a yard away from the point of explosion of a bursting shell of large calibre. He had not even been grazed by any metallic fragment and had no external wound, but at the necropsy both his lungs were found to be burst. Many deaths

under similar circumstances have been noted since the outbreak of the war, for which various more or less complicated explanations have been given. Fulminating toxic gases from the explosion and sudden nervous shock have been suggested as causes. M. Sencert points out that these hypotheses are unnecessary, and that a purely mechanical cause is a sufficient explanation.

FIRE PRECAUTIONS AND THE WAR EMERGENCY.—The British Fire Prevention Committee's special organisation to meet the war emergency completed its first half year's work this week. The work comprised mainly an extensive issue of fire warnings, the creation of a technical inquiry office to deal with all manner of technical inquiries, and the formation of a special fire survey force of 80 honorary fire surveyors entrusted with special duties, and of a special fire service force of 300 fire brigade officers and men available for mobilisation at short notice. More than 100,000 "fire warnings" in the form of small posters have been issued by the committee and distributed either directly or through the Government departments and other public authorities concerned. Such "warnings" were specially prepared for military hospitals and refugee hostels (translations in French and Flemish also being made available for Belgian wounded and Belgian refugees). There were "fire warnings" for farmers as to grain storage, for troops billeted, and for factories engaged on Government supplies.

Mr. C. D. Menzies has presented his West Linton residence of Lynehurst as a military hospital for 16 patients. The matron is Sister Campbell, and the institution will be staffed by the local members of the Voluntary Aid Detachment.

Medical News.

UNIVERSITY OF CAMBRIDGE.—On the recommendation of the State Medicine Syndicate of the University the examination for the Diploma in Psychological Medicine will not be held in the present academical year.—The following medical degree has been conferred:—

M.D.—A. E. Stansfeld, St. John's.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee 24 cases were considered and grants amounting to £290 were voted to 22 of the applicants. The following is a summary of the cases relieved:—

Widow, aged 68, of M.R.C.S. Eng. who practised in London and died in 1892. Has managed to live with the help of friends and the rent of a house, but has had to mortgage it from time to time with the result that the net income from it is very small indeed. Health very bad and is crippled with torn muscles and quite helpless. Voted £10.—Widow, aged 41, of M.B. Aberd. who practised at Easter Maubeen and died in 1914 from phthisis. Had been ill some time and was unable to provide for his wife and four children, ages 1 year to 6½ years. Only income interest on £900. Voted £10 in two instalments.—Daughter, aged 76, of M.R.C.S. Eng. who died in 1874. Practised at Plymouth. No income, but lives with widowed sister whose very moderate income has depreciated by more than one-half on account of the war. Voted £5 and recommended to apply for the Old Age Pension.—Daughter aged 24, of M.D. Edin. who practised at Stanley, N.B. Mother was for many years a grantee of the Fund. Family of six children, ages 24 to 17. Help wanted for the completion of the education of the two youngest children. Voted £10 in two instalments.—Wife of M.R.C.S. Eng., aged 36. Husband is insane, but provided for by his brother. Three children, the two eldest, ages 14 and 12, also being educated at the brother's expense. The applicant is in an advanced stage of phthisis and the youngest child, aged 9 years, is with her. They live with two aged aunts who are very badly off. Voted £18 in two instalments, £12 at once and £6 in six months.—Daughters, aged 79 and 82 years, of M.R.C.S. Eng. who practised in London. Used to earn a little by teaching music, and with the few investments they had could manage, but owing to age and ill-health have had gradually to realise their investments, and now are left penniless. Voted £12 in 12 instalments each, and recommended for annuities.—Widow, aged 64, of M.D. St. And. who practised at Camberwell, and was for some years an annuitant of the Fund. Left totally unprovided for at her husband's death this year. Three children, but none able to help. Voted £18 in 12 instalments.—M.R.C.S. Eng., aged 79 years, who practised at Camberne and other places, was hard hit by the Insurance Act, and in consequence of the war so many people have left the village that his small practice has practically gone, and has only earned about £11 during the last six months. Voted £18 in 12 instalments.—Daughter, aged 68, of M.R.C.S. Eng. who practised at Box, Wilts. Lives with a very delicate sister, who is also a grantee of the Fund. Has £12 a year from another charity, and sometimes earns about £1 per month by acting as a companion. Previous relief partly in conjunction with her sister seven times. £114. Voted £18 in 12 instalments.—Widow, aged 65, of L.S.A. Lond. who practised in London and died in

1906. Has had a severe nervous breakdown and unable to do any work. Previously was able to earn a little by nursing and needlework. Previous relief four times, £34. Voted £12 in 12 instalments.—Widow, aged 60, of M.D. Irel., who practised for 32 years at Mitcham and died in January, 1914. He was badly injured in the South African War, and lost two sons in the war. Only son, married, who partly supported the applicant, has taken a commission in the army and is now at the front, and his pay is only sufficient to keep his wife. Applicant has tried to obtain mental nursing but has not been successful. Hopes to obtain an annuity of £30 soon. Previous relief once, £18. Voted £18 in three instalments and a special grant of £10 from the War Emergency Fund.—Daughter, aged 66, of M.R.C.S. Eng. who practised at Torrington. She is unable to obtain suitable employment owing to age. No income beyond an occasional gift from friends. Relieved twice, £14. Voted £12 in 12 instalments.—Daughter, aged 48, of M.R.C.S. Eng. who practised in London. Only income £19 per annum, but has lived for many years with a friend who helped her, but is now dead. Health not good and unable to work. Previous help, £13. Voted £15 in 12 instalments.—M.D., C.M. Edin., aged 54, who practised at Wellington. Unmarried. Met with an accident in 1912, and is suffering from brain and eyesight trouble. Memory entirely gone. Lives with widowed sister whose means are very limited. Previous relief twice, £30. Voted £18 in 12 instalments.—Daughter, aged 65, of M.R.C.S. Eng. who practised at Plymouth. She has lost by the death of a friend £30 per annum. Only income now £11 12s. per annum. Rent paid by friends. Too old to work. Previous relief twice, £24. Voted £12 in 12 instalments.—Widow, aged 66, of M.D. Lond. who practised at Oxtou and died in 1897. Lost all capital in a boarding-house which proved a failure. Has endeavoured to make a living as cook, but health too bad to continue. One daughter unable to help. Relieved four times, £48. Voted £12 in 12 instalments.—Widow, aged 65, of M.R.C.S. Eng. who died in 1903. Has one son and one daughter who can only allow applicant 6s. per month. Daughter gives her her dinner daily. Too old to obtain work. Relieved 11 times, £130. Voted £12 in 12 instalments.—Widow, aged 39, of M.D. Glasg. who practised in London and died in 1910. Was left quite unprovided for at husband's death. Eyesight defective. In the summer has acted as lavatory attendant at a seaside resort, but cannot find work in the winter. Relieved once, £10, in 1910. Voted £10 in two instalments and referred to the Guild.—Daughter, aged 38, of M.R.C.S. Eng. who practised at Scarborough. Earns a little by making and selling marmalade and keeping poultry, but is so very uncertain. Relieved ten times, £97. Voted £10 in two instalments.—Daughter, aged 64, of M.R.C.S. Eng. who practised in London. Has an annuity from another charity and a friend allows her £13 per annum; total income £38. Too old to work. Relieved twice, £24. Voted £6 in 12 instalments.—Daughter, aged 53, of F.R.C.S. who practised at Bedford. She acts as a domestic servant for a small salary for the sake of the home, and no other source of income. Previous relief nine times, £64. Voted £12 in four instalments.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 11, Chandos-street, Cavendish-square, London, W.

LITERARY INTELLIGENCE.—Messrs. John Bale, Sons, and Danielsson, Limited, of Oxford House, 83-91, Great Titchfield-street, London, W., announce a work on "Defective Children," edited by Dr. T. N. Kelynnack, and consisting of a collection of 27 studies of the chief forms of defectiveness in children. The book, dedicated to Sir George Newman, is published at 7s. 6d. net.

ROYAL WEST OF ENGLAND SANATORIUM.—The annual meeting of subscribers to the Royal West of England Sanatorium, Weston-super-Mare, was held on Feb. 20th. The financial statement showed that during 1914 the income was £4869, the expenditure being £4733. The medical report stated that during the year 2460 patients have been admitted. At the commencement of the war 150 beds were placed at the disposal of the Admiralty and War Office, and up to the end of last year 500 convalescent wounded soldiers, including Belgians, had been admitted. During 1913 about 10,000 warm sea baths had been given under trained supervision and had been very beneficial in rheumatism, sciatica, &c.

MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.—The Education Committee of the London County Council has approved the renewal for the year beginning April 1st, 1915, of the arrangements made with the governing bodies of various hospitals and the committees of local treatment centres and nursing associations for the medical and dental treatment of elementary school children, subject to variations in points of detail in some of the agreements. Last year provision was made for the treatment of 106,676 cases at 46 centres; this year 125,486 cases are to be treated at 53 centres. The Children's Care Subcommittee reported that during the past year the attendance of children at the various centres had been good. From time to time additional sessions had been authorised to overcome temporary congestion. This plan had been found preferable to increasing the permanent provision for treatment, and it would be followed in the future. No material alteration was proposed in the provision for the treatment of eye, ear,

nose, and throat ailments and ringworm, but six additional dental centres were proposed, making the number 35, giving accommodation for treatment at the rate of 63,140 cases a year, as compared with a rate of 48,180 a year in the last 12 months. The total cost of the proposals was estimated at £37,500, apart from administrative charges.

THE BATTERSEA MEDICAL OFFICERSHIP.—Mr. G. Q. Lennane, medical officer of health for Battersea, having been granted a commission as lieutenant, in the 2nd London Sanitary Company, R.A.M.C. (T.F.), the health committee of his borough council have considered the matter of appointing a locum-tenent. The committee reported to the council on Feb. 24th as follows:—

We have been in communication with Dr. J. Priestley, the medical officer of health of Lambeth, and he has readily expressed his willingness to act in the absence of Dr. Lennane. Dr. Priestley has left the question of remuneration until Dr. Lennane returns to the service of the council. We recommend that, subject to the approval of the Local Government Board, Dr. Priestley be appointed medical officer of health for the borough during the absence of Dr. Lennane.

The finance committee concurred in this recommendation, but when the matter was reached the chairman of the finance committee read a letter in which the Local Government Board stated that "they have some doubt whether Dr. Priestley would be able to discharge satisfactorily the duties of medical officer in two such large boroughs without assistance" and inquired whether it would not be possible to get a properly qualified local man to act as a substitute and to arrange for Dr. Priestley to afford him advice and consult him when necessary. The chairman of the committee said there ought to be no difficulty in complying with the suggestion of the Local Government Board. The recommendation was therefore withdrawn.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—At the annual meeting of governors and subscribers to this hospital it was stated that during the past year 1787 patients had been admitted into the hospital, and 2068 had been attended in their own homes. A special feature of the work had been the treatment of the wives of our soldiers and sailors. From the outbreak of war until the end of 1914 no fewer than 160 wives of soldiers and sailors had been granted admission without the usual subscriber's letter and free of charge. Similarly 218 others had been attended in their own homes. In addition a number of Belgian refugee women had been admitted. Great difficulty had been experienced in obtaining funds for maintenance, and there was a deficiency of £1497 at the end of the year. No legacies had been received. The chairman, in moving the adoption of the report, referred to the scheme of enlargement, including out-patient department, new dining rooms, lecture room, home for district midwives and nurses, &c., which it was hoped to have been able to commence some months ago. War broke out, however, just as the committee were on the point of making a contract and it was decided to postpone the matter.

BRITISH DENTAL ASSOCIATION.—It has been decided by the representative board to hold only a business annual meeting in London this year on July 24th. An invitation had been accepted from the Wessex branch to meet at Bournemouth, under the presidency of Mr. A. E. Ball. Owing to the fact that Mr. Ball is serving as Captain in the 11th Battalion Hampshire Regiment the Bournemouth meeting has been abandoned. The board, having to choose a new president-elect, vice Mr. Ball, has unanimously appointed Mr. W. H. Dolamore, dean of the Royal Dental Hospital, who has already rendered notable service as honorary treasurer and honorary secretary of the association.

ROYAL SANITARY INSTITUTE.—At the next meeting of this institute, to be held on Tuesday, March 9th, at 90, Buckingham Palace-road, S.W., a discussion on Maternity and Child Welfare Schemes will be opened by Dr. E. W. Hope, medical officer of health of Liverpool. The chair will be taken at 7.30 P.M. by Dr. Arthur Newsholme, C.B., and the following, among others, are expected to take part in the discussion: Dr. Eric Pritchard, Dr. Eardley Holland, Dr. J. S. Fairbairn, Dr. Letitia Bernard, Dr. Annie McCall, and Dr. L. C. Parkes.

Mr. W. Pearce, 22 years of age, who was buried at St. Austell (Cornwall) on Feb. 15th, was stated to be the smallest man in England, his height being 3 ft. 6 in.

DONATIONS AND BEQUESTS.—Under the will of the late Mrs. Mary Heathfield Walls, of Daleham-gardens, Hampstead, the testatrix left £5000 to the Hampstead Home Hospital, £2000 to the London Society for Teaching the Blind to Read, and £1000 to her medical attendant.

DEATH OF MR. J. WYBRANTS OLPHERTS, DOWNPATRICK.—Deep regret has been felt in the North of Ireland at the death of Mr. J. W. Olpherts, of Downpatrick, one of its most respected practitioners. He qualified as L.R.C.P. & S. Edin. in 1869, and for many years enjoyed a large practice in Downpatrick. He was a dispensary medical officer for over 30 years, and discharged the duties with skill and kindness. For many years he was a member of the council of the Irish Medical Association, and recently he was a member of the Irish Medical Committee, in which capacity he proved a valuable colleague.

LONDON DERMATOLOGICAL SOCIETY.—A meeting of this society was held at St. John's Hospital on Feb. 16th, Dr. W. K. Sibley being in the chair.—A series of cases were shown by Dr. Morgan Dockrell, Dr. J. L. Bunch, Dr. Sibley, Mr. E. G. Reeve, and Dr. S. Gooding.—Dr. Sibley read a paper entitled "The Treatment of Diseases of the Skin and Mucous Membranes with Carbon Dioxide Snow."

Mr. Francis Martin Russell, M.R.C.S. Eng., one of the oldest medical men in the West of England, died at 13, West Mall, Clifton, Bristol, on Feb. 24th, in his ninety-sixth year. The deceased was for many years in practice at Cwmavon, Glamorganshire.

At Berwick-on-Tweed the schools have been closed until after Easter in consequence of an epidemic of measles.

A CENTENARIAN.—There has recently died in Huntingdon workhouse, at the age of 104 years, a woman named Rhoda Payne. She was a native of Spaldwich, Hunts.

Mr. Henry Stinton Lowe, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Sheriff for Anglesea.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Anti-inoculation Agitation.

THE agitation against the inoculation of the troops against typhoid has very few supporters in the House of Commons. Occasionally questions showing this bias appear on the notice paper. It is, however, the evident wish of large numbers of Members that those should be discouraged. A question on Wednesday suggesting that an investigation should be instituted into the possible connexion between inoculation against typhoid fever and meningitis and cerebro-spinal meningitis gave Mr. T. M. HEALY the opportunity to utter a brief protest. It was evident from the cheers that he had strong support in this attitude. The responsibility for passing questions before they appear on the notice paper does not rest with any Member of the Government, but with the authorities of the House.

Naval Medical Compassionate Fund Bill.

The Naval Medical Compassionate Fund Bill has been passed through all its stages in the House of Commons and been sent to the House of Lords.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 24TH.

Hitchin German Convalescent Hospital.

Mr. JOYNSON-HICKS asked the Secretary of State for the Home Department whether he had received a memorial from the chairman of the Hitchin bench of magistrates in regard to the German convalescent hospital there; whether the entire indoor staff consisted of alien enemies; whether he was aware that the hospital was situate on high ground commanding the town of Hitchin and, in particular, the Great Northern station of that town; and, seeing that anxiety was felt in the district regarding these alien enemies, would he say what steps he proposed to take.—Mr. McKENNA replied: I received a few days ago the memorial mentioned in the first sentence of the question, and it contains the statements referred to. I am inquiring into the matter.

Naval Medical Compassionate Fund Bill.

In moving the second reading of the Naval Medical Compassionate Fund Bill,

Mr. G. LAMBERT (Civil Lord of the Admiralty) said that it was a purely departmental measure dealing with a sum of £10,600, the nucleus of a fund established in 1817. Owing to various alterations in particular arrangements of the naval medical officers that fund was now in an almost moribund condition. The Bill contained provisions giving power by Order in Council to reorganise the fund and to create a number of new trustees who would probably be three—the permanent Secretary of the Admiralty, the Medical Director-General, and probably the Director of Greenwich Hospital. The object was to constitute those gentlemen trustees to enable them to consult the medical officers concerned in reference to this fund, so that the nucleus, now consisting of £10,600, might be put to better advantage and distributed amongst the dependents of naval medical officers who were killed in this war. The fund was established in 1817 with a compulsory contribution made by medical officers to supplement the pensions granted to widows, which at that time amounted only to £40 a year. Things went on until 1861, when Parliament wound up the compulsory portion of the fund, but left the voluntary part of it to be applied as a compassionate fund to the dependents of medical officers who should choose to contribute to the fund. Those medical officers had not contributed to it. There was now a sum of £10,600 available, which it was thought might be usefully employed in giving benefit to the dependents of medical officers who had been killed in the war.

The Bill was read a second time.

THURSDAY, FEB. 25TH.

Zymotic Diseases amongst the Troops.

Sir EDWARD COATES asked the Under Secretary for War whether all cases coming within the category of zymotic diseases notifiable under statute to the local sanitary authority and which occurred among the troops now undergoing training in the United Kingdom were so notified; whether such cases were removed for treatment to the isolation hospitals of the local authority in whose district they arose or were treated in camp hospital; and, in case the latter course was pursued, what steps were taken to ensure complete and efficient isolation.—Mr. TENNANT answered: Yes, Sir. A system of intercommunication exists between the civil medical officers of health and the military sanitary officers. All infectious cases are treated in local civil isolation hospitals except in a few cases where local civil accommodation is not available. Such cases are treated in special military isolation hospitals. Arrangements have also been made for the erection of pavilions in the grounds of civil isolation hospitals where existing accommodation is insufficient.

Cerebro-spinal Meningitis.

Sir EDWARD COATES asked the Under Secretary for War whether his attention had been called to the cases of cerebro-spinal meningitis among the troops in camp at Reed Hall Camp, Colchester: whether he was aware that men who had been in contact with others who had developed the disease were detained under observation in huts which closely adjoined and were part of a block in which a large number of the troops were housed; and whether he would give directions for these cases to be removed to suitable quarters properly isolated until the full period of quarantine had expired.—Mr. TENNANT said in reply: I am making inquiries into the subject of the honourable Member's question, and will in due course let him know the result.

Sir PHILIP MAGNUS asked the Secretary to the Admiralty whether similar medical arrangements to those in force at the Crystal Palace with respect to invalids suffering from cerebro-spinal fever were or would be made in the case of invalids similarly affected in the Royal Naval Hospital, Chatham.—Mr. MACNAMARA wrote in reply: The Crystal Palace and the Royal Naval Hospital, Chatham, are not comparable establishments. The former is a training establishment for sound men, the latter a hospital where sick men are treated. Consequently patients suffering from cerebro-spinal meningitis and contacts with such cases are at once removed from the first, whereas patients and contacts are received into the latter. Naturally every possible precaution is taken at the Royal Naval Hospital, Chatham, to prevent the disease spreading to any other patient. They are, of course, treated in the infectious, not the general, hospital.

A Case of Small-pox in the Army.

Mr. W. THORNE asked the Under Secretary for War whether he would state the condition as regarded vaccination and revaccination of the British soldiers who suffered from small-pox in the United Kingdom between August 1st, 1914, and Jan. 31st, 1915.—Mr. TENNANT answered: The history of the solitary case of small-pox which has occurred

between the dates mentioned in the question is as follows: The soldier referred to, who was vaccinated in infancy, enlisted on August 10th last, went into hospital on August 13th, and was removed to an infectious hospital on the following day. Had he not been taken ill so quickly after enlistment he would have been revaccinated.

Antityphoid Inoculation.

Mr. W. THORNE asked the Under Secretary for War whether he would state the condition as regarded inoculation of the 625 cases of and 49 deaths from typhoid fever amongst the Expeditionary Force from the beginning of August, 1914, to Feb. 11th, 1915, and of the 262 cases of and 47 deaths from typhoid fever amongst the British troops in the United Kingdom from August 1st, 1914, to Jan. 31st, 1915.—Mr. TENNANT replied: I am arranging to have the information asked for by my honourable friend compiled, but it may well take some time to prepare. I shall let my honourable friend know the result as soon as it is ready.

MONDAY, MARCH 1ST.

Consultant Surgeons and Physicians with the Expeditionary Force.

Mr. LYNCH asked the Under Secretary for War whether he could give the names of British consultant surgeons and physicians engaged in medical work with the Expeditionary Force in France or in Belgium, indicating those whose services had been accepted on account of the present war, but who would not otherwise have been called upon in the way of routine service with the army; whether there was a regular scale of payment of these consultants; and, if so, what was the rate.—Mr. TENNANT wrote in reply: The following is a list of the British consultant physicians and surgeons employed in France and Belgium: Sir G. H. Makins, K.C.B., F.R.C.S., Sir A. A. Bowlby, Knt., C.M.G., F.R.C.S., Sir W. P. Herringham, Knt., M.D., Sir A. E. Wright, Knt., M.D., F.R.C.S., F.R.S., Mr. F. F. Burghard, M.D., F.R.C.S., Sir J. Rose Bradford, K.C.M.G., M.D., F.R.S., Mr. W. T. Lister, M.B., F.R.C.S., Sir B. E. Dawson, K.C.V.O., M.D., Sir B. G. A. Moynihan, Knt., M.B., F.R.C.S., and Mr. H. M. W. Gray, M.B., F.R.C.S. Edin. With the exception of Sir A. E. Wright and Mr. Lister these gentlemen are officers of the Territorial Force, and were commissioned before the war. They now hold the temporary rank of Colonel in the Army Medical Service and receive the pay of that rank. They were all appointed consultants on account of the present war, and their services in that capacity have been most useful.

Antityphoid Inoculation.

Mr. BENTHAM asked the Under Secretary for War whether a record was kept of the condition as regarded inoculation of every soldier; if not, how were the statistics compiled showing the condition as regarded inoculation of men who contracted typhoid fever; and if such record was kept, why was not information concerning the condition of soldiers as regarded inoculation available when they developed diseases which were certified as other than typhoid fever.—Mr. TENNANT furnished the following written answer: Instructions have been given for these records to be kept, but as the compilation of these statistics would entail a considerable amount of labour, I regret that in the present pressure of work I do not feel justified in placing this additional strain upon the medical officers of my department.

Replying to a series of questions put by Mr. CHANCELLOR, Mr. TENNANT said that the average death-rate from typhoid per 1000 strength amongst British troops in India for certain years was as follows:—

1895 ... 5.61 per 1000 strength.	1899 ... 5.14 per 1000 strength.
1896 ... 6.31	1900 ... 4.77
1897 ... 8.62	1903 ... 4.19
1898 ... 10.04	

The earliest known inoculation against typhoid in the British army in India was in 1898. This was an initial attempt which was discontinued after the South African War, and it was reintroduced in 1905. With regard to the 262 cases of typhoid among the troops in the United Kingdom from August 1st, 1914, to Jan. 31st, 1915, 25 were inoculated and 237 uninoculated. Of the 47 deaths 2 were inoculated and 45 uninoculated.

Cholera Vaccine Treatment.

Answering Mr. ROWLANDS, Mr. TENNANT stated that nothing was known at the War Office of inoculation against typhus, but as regarded cholera vaccine treatment was regularly carried out in India in face of epidemics, and in the event of an outbreak of cholera the War Office had ample supplies of the vaccine ready for immediate use.

Hospital Accommodation for Contagious Disease.

Sir CUTHBERT QUILTER asked the Under Secretary for War whether it was proposed to take over the workhouse institution at Kedington, near Haverhill, as a hospital for soldiers suffering from a contagious disease; whether he was aware of the objection to this course taken by the guardians of the Risbridge union; and whether, in the circumstances, he

would arrange for other accommodation to be obtained.—Mr. TENNANT answered: It was proposed to take over this institution as a hospital, but as the local authorities objected other accommodation has been arranged.

Pay of the Royal Army Medical Corps.

Sir JOHN LONSDALE asked the Financial Secretary to the War Office why officers of the Royal Army Medical Corps drew their pay one month in arrear, whereas other officers in the army drew their pay one month in advance by regulation; and whether the practice throughout the army would be made uniform in this respect.—Mr. H. BAKER replied: Officers of the Royal Army Medical Corps are not peculiar in this respect. They are paid in arrear in common with all staff and departmental officers. Only regimental officers draw in advance. This is in accordance with a long-standing custom which it is not proposed to disturb.

An Outbreak of Meningitis.

Mr. JOYNSON-HICKS asked the Secretary to the Admiralty how many of the 14 medical men attached to the Royal Naval Division at the Crystal Palace had, since the outbreak of meningitis, been drafted, with the battalions to which they were attached, to Blandford; how many more would shortly be drafted; and how many would be left at the Crystal Palace.—Mr. MACNAMARA replied: Nine of the medical officers attached to the Royal Naval Division at the Crystal Palace have been drafted with their battalions. Two have been sent in lieu, thus leaving seven medical officers for about 5000 men. It is not contemplated that any more should be drafted at present.

Mr. JOYNSON-HICKS further asked whether the bacteriologist who had been specially appointed to inquire into the causes of the outbreak of meningitis was not specially appointed at all but was one of the ordinary doctors attached to the Naval Division; and whether he had since been drafted to Blandford.—Mr. MACNAMARA answered: The bacteriologist specially appointed to inquire into the outbreak is not one of the ordinary doctors attached to the Naval Division, nor has he been in any way connected with the Division, but is the professor of clinical pathology at the Naval Medical School at Greenwich. Naturally he has not been drafted to Blandford.

Mr. JOYNSON-HICKS also asked whether two officers of the Royal Naval Division died from meningitis last week at their own homes; whether any further cases had occurred; and how many men were still at the Crystal Palace.—Mr. MACNAMARA said in reply: One case, not two, of cerebro-spinal meningitis from the Royal Naval Division at the Crystal Palace has died at his own home. Up to to-day there had been 18 cases in all with 13 deaths. There are about 5000 men still at the Crystal Palace.

Temporary Surgeons in the Royal Navy.

Lord CHARLES BERESFORD asked the Secretary to the Admiralty whether he could now make a statement with regard to the position of temporary surgeons in the Royal Navy.—Mr. MACNAMARA answered: The question has been carefully considered, but it has not been found possible to arrive at a satisfactory solution of the difficulty referred to by the noble lord in his question of Feb. 18th.

The Prevention of Insanity.

Mr. W. THORNE asked the President of the Local Government Board whether the Report on the Prevention of Insanity had been published in accordance with his promise that he made to a deputation which waited upon him on Thursday, July 16th, 1914; whether he was aware that over 300 Members of the House of Commons and about 236 of the medical profession signed a petition against the principles contained in Part V. of the London County Council (General Powers) Bill; and whether the Government intended taking any action in the matter.—Mr. HERBERT SAMUEL said in reply: The outbreak of the war prevented any action being taken at the time. I have lately given fresh consideration to the question, but have come to the conclusion that an expert inquiry must precede any definite action. I propose to appoint a committee for this purpose when circumstances permit.

TUESDAY, MARCH 2ND.

Communications from Wounded in France.

Answering Lord ROBERT CECIL, Mr. TENNANT said: Official postcards are supplied so that the sick and wounded in the hospitals in France may inform their relatives that they have been admitted. At present the postcard is only allowed to contain a statement of the official number of the hospital and not of the place where it is situated. The military authorities in France have, however, been asked to reconsider the form of the card with a view to the inclusion of the name of the hospital.

Repatriation of Medical Men.

Replying to Lord ROBERT CECIL, Sir EDWARD GREY (Secretary of State for Foreign Affairs) said: Civilian doctors and civilians not of military age—that is, under 17 and over 55 years of age in the case of Germany, and under 18 and

over 55 years of age in the case of Austria—are entitled to repatriation under the agreements concluded between His Majesty's Government and the German and Austro-Hungarian Governments. So far as our information goes, these agreements have been observed by the Governments concerned, but in a certain number of cases in which proof of age or confirmation of a claim to be a member of the medical profession was not immediately forthcoming special representations have been made by the Government concerned.

WEDNESDAY, MARCH 3RD.

Inoculation.

Mr. YEO asked the Under Secretary for War whether, in view of the prevalence of meningitis and cerebro-spinal meningitis and of the percentage of deaths that had resulted therefrom amongst British troops in the United Kingdom since the outbreak of war, he would recommend that a careful investigation be instituted into the possible connexion between inoculation against typhoid fever and the diseases first mentioned.—Mr. TENNANT replied: Experts, both military and civilian, have been consulted on this point. They are of opinion that there is no connexion between inoculation and cerebro-spinal meningitis, and in the circumstances it is not considered desirable to institute any special investigation.

Mr. T. M. HEALY: As this is not the first time that the paper has contained questions of this sort, and as nearly everybody knows this suggestion is false, will the right honourable gentleman do something to discourage the putting down of these questions?

HON. MEMBERS: Hear, hear.

Mr. TENNANT: I sympathise very much with the honourable and learned gentleman. It is, however, a matter for the authorities of the House and not for me to decide what questions should be put down.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

AYSHFORD, GILES REYNOLDS, M.B., C.M. Edin., has been appointed Medical Officer and Public Vaccinator for the Dalwood and Stockland Districts by the Axminster (Devon) Board of Guardians.
BRYAN, CHARLES H., L.R.C.P. & S. Irel., has been appointed Medical Officer for Kiltegan District Dispensary by the Baltinglass Board of Guardians.

Notes, Short Comments, and Answers to Correspondents.

VERMIN IN THE TRENCHES.

To the Editor of THE LANCET.

SIR,—Since last October I have had to prepare many remedies for the destruction of body parasites, which, owing to the enforced conditions of life in the trenches, have severely infested our soldiers. The drugs used have been the usual ones: sassafras, eucalyptus, aniseed, and various dusting powders which owe their efficacy in most cases to their volatility. The antiparasitic action of mercury has long been recognised, but its method of application not being idealistic, experiments were made to devise a more suitable and cleanly method of exhibition. The following has given such satisfactory results as to warrant its publication:—

R Hydrargyri ammoniati	3 i.
Zinci oxidi	3 ss.
Magnesi silicatis	3 ss.
Fiat pulvis.	

The powder is thoroughly applied to the infested areas on a lint pad or by medium of the pepper-box arrangement suggested by Mr. J. F. Briscoe in THE LANCET of Feb. 20th; being non-greasy the necessity for shaving the infested part is avoided. The mercurial salt being very slowly ionised, and the astringent and dehydrating effect of the oxide of zinc inhibiting absorption, no toxic effects are produced, but an increased localised action is obtained. The French chalk is added to increase the diffusibility of the powder on application, making it closely resemble a toilet powder. The absence of fatty acids is much appreciated by the patients, staining of the clothes being quite avoided.

I have seen the powder applied to suppurating wounds infested with vermin with the result that in two days both parasites and ova have disappeared, and the patients' mental and physical condition have been considerably improved. I have repeatedly tested the saliva and urine of patients undergoing the treatment, and have not been able to find the slightest evidence of the general absorption of the mercury, nor have I seen that painful dermatitis produced, which so often follows the application of a mercurial salt; the zinc oxide probably corrects any tendency it might have to do so. I would urge the value of the powder from a prophylactic standpoint also; dusted on the vests, pants, shirts, or body it is inimical to the development, not only of vermin, but of other organisms to which our virile defenders are exposed.

I am, Sir, yours faithfully,

LANGFORD MOORE.

St. Bartholomew's Hospital, E.C., Feb. 26th, 1915.

"THE HIDEOUS SIN."

IN the *Weekly Dispatch* of Feb. 21st Mr. Robert Blatchford under this title quoted from an article which appeared in the same paper on Feb. 14th, written by Mr. Max Pemberton, in which the latter writer says: "THE LANCET supports the statement that from one particular convent of 60 some 29 are expecting children." We did not "support" the statement or make the statement. It occurred in a public address which was duly reported last December in THE LANCET and other newspapers. Very many terrible things have been done in unhappy Belgium, and we no more contradict the statement quoted by Mr. Max Pemberton than we have supported it; but we are bound to point out that Mr. Max Pemberton made a careless use of our name, and one that has naturally caused us a great deal of inconvenience.

WANTED, A HOME.

To the Editor of THE LANCET.

SIR,—I should be grateful if any of your readers could inform me of a home or institution where a "Mongolian" child, aged 3, could be placed. The parents are gentlefolk, but with very limited means.

I am, Sir, yours faithfully,

C. WILLETT CUNNINGTON.

Dollis-avenue, Finchley, N., Feb. 27th, 1915.

MEAT FOR THE SOLDIER.

IN THE LANCET of June 16th, 1906, we published an annotation under this heading commenting on the form of tender for contracts to the army and the question of "home-fed" and "foreign-fed" meat to be supplied to the army. The amount of the meat supplied to our soldiers and sailors at that time was said to be something like £2,000,000 worth per annum; what must it be, then, with the present enormously increased army of this country? The question of meat contracts must affect the supply and breeding of cattle not only in this country, but very largely in the colonies and the Argentine. The refrigerating process

comes up for reconsideration *versus* the importation of live cattle to be killed here on arrival, for it is known that long sea journeys by no means improve the beast or its meat. The recent trouble arising from the supply of a small quantity of meat by a firm of contractors in London tends to suggest that attention will have to be given anew to the whole question in view of the tremendously altered circumstances of the army and its supplies.

SUPPLY AND DEMAND.

To the Editor of THE LANCET.

SIR,—One hears that owing to the number of doctors who have gone to help in the war there is a serious dearth of doctors in some towns and country districts. Could you or any of your readers inform me if this is actually the case, and how I could discover places in which the population are suffering from want of medical men? I have practised abroad for some years and am forced to remain in England owing to the war, and should be glad to find a place such as I have described. I am too old for military service and something of an invalid, but am capable of a fair amount of work, and being married desire to establish a home preferably in the West Country, Devon or Cornwall especially.

I am, Sir, yours faithfully,

Feb. 19th, 1915.

DOCTOR OF MEDICINE.

To the Editor of THE LANCET.

SIR,—The question of an alleged shortage of medical men is receiving a good deal of attention in the press; in certain dailies it has assumed the dimensions of a campaign appealing to women to matriculate in medicine and qualify. Suggestions have even been made to reduce the qualifying standards of examinations and to permit of the employment of unqualified assistants with the view to meet the alleged "scarcity of doctors." Could not the present temporary shortage be met by a system of organised distribution applied to the medical civil services? It was stated last week on the authority of Sir Donald MacAlister that there existed a superabundance in some places and a deficiency in others. How could it be otherwise from a consideration of the relative value of appointments open to recently qualified men? House appointments in hospitals and infirmaries and other charitable institutions at a purely nominal remuneration, competing with the County Council services (e.g., tuberculosis, school, and asylum junior medical officers) offering salaries of £250 and £300 with substantial emoluments, and in many instances with less onerous work.

Since last August the great majority of recently qualified men have taken temporary commissions in the forces. In many instances in the asylum and other County Council services junior medical officers have also done so, but in such cases the authorities have almost invariably advertised for a locum-tenent (where the appointment is kept open) at "6 guineas per week all found." This in no way relieves the strain of shortage.

This kind of thing could only result in a waste instead of an economy of medical workers and of money. The smaller hospitals and infirmaries are outbidden, and as a result find it difficult to secure medical officers. Under the great strain of present conditions one would think that, without loss to the community or to the profession, the junior medical officers of asylums and other county medical services could *pro tem.* be spared, their services being utilised where most urgently required. This would provide a good number of men and would help to reduce the dislocation of medical service to a minimum. Many asylums have large medical staffs ranging from six to three assistant medical officers. As to the question of a shortage five or six years hence, to which so much attention has been directed in the daily press, it can at least for the present be left to take care of itself. Of the thousands of recently qualified men holding temporary commissions the majority will return to civil practice or appointments. My card is enclosed.

I am, Sir, yours faithfully,

Feb. 15th, 1915.

L.R.C.P.

* * Our correspondent "L.R.C.P." in his otherwise sensible letter forgets that a shortage in the medical profession five or six years hence can only be averted by an increase of students now.—ED. L.

THE TAI-NAN HOSPITAL, FORMOSA.

IN the medical report of the English Presbyterian Mission Hospital at Tai-Nan, Formosa, 1914, Dr. James L. Maxwell refers especially to an outbreak of typhoid fever. In connexion therewith he expresses the opinion that the bulk of the anomalous attacks of non-malarial continued fever in children are really enteric, that the temperature chart in such cases is no guide, but is apt to lead the observer astray, because where malaria is common a malarial pyrexia is liable to complicate almost any ailment, and even the Widal reaction often fails to give a satisfactory result. The question arises as to the existence of typhus among the Chinese residents of Formosa. Dysentery

is quite common, many cases being bacillary or mixed; in the former emetine proves useless, except, perhaps, for some slight amelioration of symptoms. Rogers' albugin treatment in bacillary cases has proved disappointing in Dr. Maxwell's hands. The surgical work is extraordinarily varied, and the surgeon has to undertake practically every kind of operation. Two cases of severe injury to the cervical spine are reported, as are also cases of vesical calculus and extra-uterine pregnancy. The medical report and particularly the summary of operations, which reach a total of 2201, are very creditable to Dr. Maxwell and his associate, Dr. G. Gushue-Taylor, while the fact extracted from the hospital statistics that the hospital treated 2062 in-patients, while the total expense of the institution was only 10,358 yen, or approximately £1065 a year, is remarkable.

WILLING TO HELP.

To the Editor of THE LANCET.

SIR,—Noticing from time to time letters in THE LANCET asking for medical officers in one unit and another I shall be glad to hear of any suitable position either at home or abroad where it is thought my services and experience can be made use of with the greatest advantage. I am medical officer of health to a metropolitan borough with 20 years' experience in such work, have also some military experience, and can provide, ride, and drive horse and motor car should such be of use. Full particulars can be forwarded.

I am, Sir, yours faithfully,

Feb. 28th, 1915.

WILLING TO HELP.

HEALTH OF BRITISH HONDURAS.

In his report on the Blue-book for 1913 Mr. Robert Walter, Colonial Secretary, states that the year was unusually wet; in fact, the rainfall (126.73 inches) was almost the heaviest for the last ten years, but the public health was good, and no serious epidemic of any kind occurred. Small-pox has not been in the colony since 1909, and there have been no cases of yellow fever since 1905, whilst plague may be said to be unknown. Tuberculosis showed little sign of diminution; it is due principally to overcrowding and neglect of elementary laws of health, and it is hoped that increasing knowledge, with improved housing conditions, will do much towards reducing the scourge. The estimated mean population for the year was 41,170—20,689 males and 20,481 females. The average population of the whole colony to the square mile is 4.83. The most populous district is Belize, with 9.49 to the square mile, and the least populous Toledo, with only 1.97 to the square mile. The birth-rate for the year was 40.151 and the mortality 26.233 per 1000. The number of illegitimate births was 709 out of a total of 1653, or 42.90 per cent. The daily average number of patients under treatment in Belize Hospital was 48.25; in Corozal Hospital, 7.74; in Orange Walk Hospital, 4.20; in Strann Creek Hospital, 4.99; and in Punta Gorda Hospital, 6.4.

CENTIGRADE AND FAHRENHEIT.

To the Editor of THE LANCET.

SIR,—In reference to Quatorze, M.D.'s letter in THE LANCET of Feb. 27th on Centigrade and Fahrenheit scales, I thought we had most of us learned the relations between the two scales, and the fact that one begins at the freezing-point and the other 32° F. lower, and it is a simple thing to work out the correspondence if we sit down with pen, ink, and paper. What the British doctor really wants are ready memoranda of the facts and relations which most nearly concern his daily clinical work and professional reading. Now, 95° Fahrenheit corresponds to 35° Centigrade, and 104° F. to 40° C. The two fives in the first case and the two fours in the second supply the *memoria technica*. From these it is easy to calculate all the intermediate relations, remembering that 1° C. equals 1.8° F. Thus 36° C. equal 96.8° F., 37° C. equal 98.6° F., and so on, and we rarely have to work outside these nine degrees Fahrenheit or five degrees Centigrade. Those with "good heads for figures" can learn them by heart. It will be seen that 37° C. is just above the 98.4° F., which is commonly regarded as the normal temperature; also that from 36° C. to 37° C. covers from 96.8° F. to 98.6° F. an interval which runs only a fifth of a degree Fahrenheit above and below the daily range of temperature in health—namely, from 97° to 98.4°.

I am, Sir, yours faithfully,

March 2nd, 1915.

GRIMPEUR.

MEDICAL REPRESENTATION ON THE BATTERSEA BOROUGH COUNCIL.

It was mentioned at a meeting of the Battersea borough council last week that there is now no medical practitioner among the members of that body. In former times there have been as many as three or four. The council decided to record its regret at the death of Dr. J. T. Richards, who died on Feb. 18th after a very short

illness. One member said that his colleagues had hoped that if an emergency were to arise during the absence of the medical officer they might have the advice and assistance of Dr. Richards, but Providence had ruled it otherwise. Dr. Richards was a member of the council for many years. His quiet, earnest personality and his proved ability made him respected by all his colleagues, though his amused attitude towards many borough council conventions rendered him sometimes a puzzle to the body that set up the brazen image of the "Little Brown Dog."

Cheval.—Allowing for depreciation and for interest on capital, it is doubtful whether our correspondent could run a motor-car on his exceptionally small mileage for less than his present outlay for the hired horse and brougham, even though he has a place in which he could keep the car and would drive himself. But given a mechanical turn of mind, he would find the car much more interesting, and it would enable him to extend his sphere of operations if desirable. For the sum mentioned, a good secondhand small car would be best, but care should be taken as to where and from whom the purchase is made, and our correspondent should not trust his own judgment. A clearance of 6 ft. 6 in. is somewhat close, but should not present difficulty with a small car—and care. Better to "back in," so as to be ready to come out quickly in case of an urgent call, especially in the dark. The car is a "sure scorer" in urgent cases.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Papers:—Mr. E. Heron-Allen: Contributions to the Study of Bionomics and Reproductive Processes of the Foraminifera (communicated by Prof. W. A. Herdman).—Mr. G. E. Nicholls: On the Occurrence of an Intracranial Ganglion upon the Oculomotor Nerve in Scyllium Canicula, with a Suggestion as to its Bearing upon the Question of the Segmental Value of Certain of the Cranial Nerves (communicated by Prof. A. Dendy).—Prof. R. Kennedy: Experiments on the Restoration of Paralyzed Muscles by Means of Nerve Anastomosis. Part III., Anastomosis of the Brachial Plexus, with a Consideration of the Distribution of its Roots (communicated by Prof. J. G. McKendrick).—Mr. A. F. S. Kent: On the Mechanism of the Cardiac Valves. A Preliminary Communication (communicated by Prof. C. S. Sherrington).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

FRIDAY.

CLINICAL SECTION (Hon. Secretaries—Thomas H. Kellock, David Forsyth): at 8 P.M.

Dr. J. Porter Parkinson: Case of Tumour of the Neck with Obstruction of the Superior Vena Cava. And other Cases.

HUNTERIAN SOCIETY.

WEDNESDAY.—4 P.M., Clinical Afternoon at the Royal Hospital for Diseases of the Chest, City-road, E.C. Cases will be shown by Dr. A. T. Davies, Dr. R. M. Leslie, Dr. D. B. King, and Dr. L. Maitland. Cardiograph Demonstrations:—Dr. A. W. Stott. Epidiascope and Fluorescent Screen Demonstrations:—Dr. A. C. Jordan. Pathological Demonstrations:—Dr. C. Dickinson.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

WEDNESDAY.—8 P.M., Mr. J. W. Gordon: Patent Law Reform and the War.

SOUTH-WEST LONDON MEDICAL SOCIETY, Bolingbroke Hospital, Wandsworth Common, S.W.

WEDNESDAY.—9 P.M., Mr. M. S. Mayou: Conjunctivitis, its Varieties and Treatment. (Lantern demonstration.)

CHILD STUDY SOCIETY LONDON, Royal Sanitary Institute, 90, Buckingham Palace-road, S.W.

THURSDAY.—6 P.M., Discussion on the Care and Development of the Child—During School Age. Treatment Centres and their Possibilities, Miss M. McMillan; Care Committees, Mrs. Evelyn.

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.

THURSDAY.—8.30 P.M., Harveian Lecture:—Sir St. Clair Thomson: Modern Methods in Rhinology-laryngology (illustrated by lantern slides).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Hunterian Lecture:—Prof. W. S. Handley: Ileus Duplex (Inflammatory Enterocolic Ileus).

WEDNESDAY.—5 P.M., Hunterian Lecture:—Prof. J. H. Evans: Some Congenital Lesions of the Small Intestine, their Origin, Clinical Bearings, and Treatment. (Illustrated by specimens and the epidiascope.)

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 11 A.M., Mr. Souttar: Demonstration of Minor Operations. 12 noon, Lecture:—Mr. Souttar: Abdominal Diagnosis. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 12 noon, Lecture: Dr. G. Stewart: Neurological Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynaecological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. Bernstein: Applied Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 12 noon, Lecture:—Mr. Souttar: Surgical Anatomy of the Abdomen. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Gynaecological (Dr. J. B. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. Howell Evans); Nose, Throat, and Ear (Mr. H. D. Gillies). X Rays and Electrical Methods (Dr. Metcalfe). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Clinical Demonstration: Mr. H. W. Carson: Selected Surgical Cases.

WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. Brooks).

THURSDAY.—2.30 P.M., Gynaecological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson); X Rays and Electrical Methods (Dr. Metcalfe).

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: The Popular Eruptions.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

FRIDAY.—9 P.M., Sir Rickman J. Godlee: Back to Lister.

ROYAL SANITARY INSTITUTE, 90, Buckingham Palace-road, S.W.

TUESDAY.—7.30 P.M., Discussion on Maternity and Child Welfare Schemes, opened by Dr. E. W. Hope (Liverpool).

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1914 were given in THE LANCET of Dec. 26th, 1914.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1914 are now ready. Bound in cloth, gilt lettered, price 16s., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.	TO THE COLONIES AND ABROAD.
One Year £1 1 0	One Year £1 5 0
Six Months 0 12 6	Six Months 0 14 0
Three Months 0 6 6	Three Months 0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

I.—Mr. K. E. Ingram-Johnson, Stanley; *Interstate Medical Journal*, St. Louis.

J.—Mr. J. W. Jones, Manchester.

K.—Dr. J. S. Kellett-Smith, Eastbourne; Kapurthala, India, Chief Medical Officer of.

L.—Dr. D. Lee, Kettering; Mr. T. Laffan, Cashel; Leicester Education Committee, Secretary of; Sir H. B. Longhurst, Hampton Hill; Mr. T. S. Logan, Stone.

M.—Mr. F. Mitchell, Uckfield; Mr. G. E. Mould, Rotherham;

Manchester Eye Hospital, Secretary of; Messrs. Mather and Crowther, Lond.; Manchester Corporation, Accountant to the; Morgan's Library, Brighton; Medical Correspondence College, Lond.; Dr. P. R. Mander, Lond.; Macclesfield General Infirmary, Secretary of.

N.—Newcastle-upon-Tyne Education Committee, Treasurer to the; Newcastle-upon-Tyne Corporation, Accountant to the.

O.—Captain A. P. O'Connor, R.A.M.C., France; Oxford Eye Hospital, Secretary of; Messrs. Oppenheimer, Son, and Co., Lond.

P.—Messrs. G. Pulman and Sons, Lond.; Mr. F. J. Pearson, Oswestry; Mr. F. G. Pulman, Lond.; Practitioner, Battersea; The Public Trustee, Lond.

R.—Surgeon A. K. Roche, R.N., Lond.; Dr. A. Routh, Lond.; Royal College of Physicians of Ireland, Dublin, Registrar of; Royal Victoria Infirmary, Newcastle-upon-Tyne, Secretary of; Royal Eastern Counties Institution, Colchester, Secretary of; Royal Samaritan Hospital for Women, Glasgow, Secretary of; Rochester, &c., Stationery Co., Secretary of; R. C. B.; Mr. Rattray, Haslemere; Mr. J. H. Ray, Manchester.

S.—Mr. W. B. Saw, Lond.; Mr. Gilbert Smith, Birmingham; Messrs. Spiers and Pond, Lond.; Messrs. W. H. Smith and Son, Lond.; Lieutenant-Colonel A. W. Sheen, Netley; St. Mary's Hospital for Women, &c., Plaistow, Secretary of; Mr. A. Stenhouse, Glasgow; Messrs. H. Squire and Co., Lond.; Smedley's Hydropathic Establishment, Matlock; Dr. D. Salaman, Bilbeis, Egypt; Dr. J. A. Struthers, Booter's Swansea, &c., Hospital, Secretary of; Mr. W. Stuart-Low, Lond.; Mr. E. A. Shirvell, Padstow; Messrs. Slattex and Rose, Oxford; Mr. A. E. Sumner, Lisbon.

T.—Mr. J. Tubb Thomas, Trobridge; Mr. W. Thompson, Leeds; Messrs. W. Thacker and Co., Lond.; Trinity College, School Physic, Dublin, Registrar of; Messrs. Tindall and Jarrold, Chelmsford.

V.—Messrs. Van Houten, Lond.

W.—Mr. A. Whitty, Castle Eden; Mr. T. F. Wyse, West Mallin; Dr. L. Wainwright, Folkestone; Mr. P. Wood, Crawley; Wals Education Committee, Clerk to the; Western Newspaper Co., Plymouth, Manager of; Dr. J. Wait, Tynemouth; Wye House Buxton, Medical Superintendent of; West Kent General Hospital, Maidstone, Secretary of; Mr. Wright, Lond.; Dr. R. F. Ward, Harrogate.

Y.—Dr. M. Young, Chester.

Hunterian Lecture

ON

THE OPERATIVE TREATMENT OF CLEFT PALATE.

Delivered before the Royal College of Surgeons of England on Feb. 17th, 1915.

By H. BLAKEWAY, M.S. LOND., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR AT THE COLLEGE; SURGICAL REGISTRAR, ST. BARTHOLOMEW'S HOSPITAL; SURGEON, WITH CHARGE OF OUT-PATIENTS, VICTORIA HOSPITAL FOR CHILDREN; ACTING ASSISTANT SURGEON, ROYAL FREE HOSPITAL.

(Concluded from p. 482.)

RESULTS IN 100 CONSECUTIVE CASES TREATED BY LANE'S OPERATION.

THE discussions of the subject during the last 10 years or so have brought forth many appeals for evidence as to the alleged advantages of the flap operation, and it has become urgently desirable that statistics should be produced, and that such figures should supply, not merely the immediate results of the operation, but also the ultimate results as seen at intervals of several years after its performance. I desire especially to acknowledge my indebtedness to Sir Arbuthnot Lane and to the authorities at Great Ormond-street Hospital, through whose kindness I have been enabled to investigate 100 consecutive cases treated by this method. (Table III.)

These patients were operated upon between April, 1905, and January, 1907. They have been traced, and, if possible, seen at intervals after the operation varying between approximately 5 and 9½ years. After such intervals conclusions may justly be drawn as to the effect of the operation upon the speech as well as upon the healing of the palate.

The cases may be summarised as follows: Males, 48; females, 52. Of these 100 cases 87 have been traced, and of these 40 have been seen; 1 of these has since died. Of the remaining 47 cases, 33 are dead, and in 14 the result of the treatment was ascertained by correspondence.

The ages of the patients at the time of the first operation varied from 1 day to 11 years, but 79 of the children were under the age of 1 year.

The cases showed the following degrees of severity:—

Complete cleft of hard and soft palates	35 cases.
Cleft of soft and part of hard palate	45 "
Cleft of soft palate only	11 "
Congenital central cleft of palate	1 case.

In the remaining 8 cases the extent of the cleft was not stated in the notes and could not afterwards be determined.

Mortality of the Operation.

Of the children 33 died. It is impossible always to write with certainty as to the cause. While some of the deaths were certainly due to the operation, and others as certainly not, there remain cases in which differences of opinion might arise as to the part which the operation played in producing the fatal result. Since cases were not excluded on account of malnutrition, of necessity some deaths are recorded as due to the operation which would almost certainly have occurred even if no operation had been performed. Allusion has already been made to the importance of this factor of difference in the results obtained at different hospitals and by different surgeons.

Of the 33 deaths 19* are judged to have been due

* Cases 9, 19, 26, 33, 35, 43, 46, 50, 52, 58, 60, 78, 83, 90, 91, 94, 97, 98, and 100.

to the operation; 13 of these resulted from first operations and 6 from second or later operations.

In estimating the mortality of the treatment attention must be paid not only to the deaths resulting from first operations, but to the death-rate of any necessary secondary operations as well. Since at least 40 per cent. of the series required secondary operations the mortality of the treatment cannot be less than $13 + 3.2$ —i.e., 16.2 per cent. (there were 75 secondary operations, with 6 deaths, a mortality for secondary operations alone of 8 per cent.); and it must actually be somewhat greater than this because many of the patients were exposed to the 3.2 per cent. risk several times (some of the patients underwent as many as five or six operations). It is fair to point out, however, that many of these children had a harelip operated upon at the same time as the cleft palate, and it is uncertain to what extent the operation on the lip contributed to the child's death; at any rate, operations on bad cases of harelip have a mortality of their own.

There is no great dissimilarity in the mortality rate for operations upon the different classes of cleft until we come to clefts of the soft palate only; in these the mortality is distinctly lower than in the more severe cases.

For complete clefts there were—

35 primary operations, with 5 deaths	= 14.28 per cent.
33 secondary " " 3 " "	= 9.0 " "

For clefts of soft and part of hard palate there were—

45 primary operations, with 6 deaths	= 13.3 per cent.
39 secondary " " 1 death	= 2.56 " "

For clefts of soft palate only there were—

11 primary operations, with 1 death	= 9.0 per cent.
-------------------------------------	-----------------

The secondary operations for clefts of the soft palate were too few for conclusions to be drawn from them.

One death from a primary operation and one after a secondary one occurred in cases in which the extent of the cleft was not stated in the notes.

Probably the above data represent the mortality from secondary operations at rather too high a figure, for almost certainly some cases underwent a larger number of secondary operations than appeared in reading the notes of a limited period of years. As regards the causes of death, pneumonia and diarrhoea and vomiting had the chief share.

It is instructive to note that in 9 cases death took place shortly after the child had returned home; and further, in view of the statement that operations for cleft palate in early infancy are not attended with special danger, that among 44 first operations for all varieties of cleft, under the age of 3 months, 9 were fatal, a percentage of 20.45; whereas of 56 first operations upon children over that age only 4 resulted fatally, a percentage of 7.14. It must be borne in mind that it is for use in early infancy that the operation has been specially designed. Of lesser complications 2 cases (Nos. 74 and 76) of recurrent hæmorrhage occurred.

We have next to consider

The Results as regards Closure of the Cleft.

Reliable data as to this point can only be obtained by confining attention to the patients who have been seen. Although the parents of the children could perhaps be trusted to note correctly whether the hard palate was or was not completely healed, experience showed the futility of trusting to their statements about the soft palate.

The results in these 40 cases were as follows:—

(a) 15 cases of complete cleft of hard and soft palates:—			
Complete closure...	After one operation	...	3
	" more than one operation	...	4
Partial closure	After one operation	...	2
	" more than one operation	...	6
(b) 19 cases of cleft of soft and part of hard palate:—			
Complete closure...	After one operation	...	4
	" more than one operation	...	4
Partial closure	After one operation	...	4
	" more than one operation	...	4
Failure	After one operation	...	1
	" four operations	...	1
(c) 6 cases of cleft of the soft palate only:—			
Complete closure...	After one operation	...	3
Partial closure	After one operation	...	3

Several of the cases described as "partial closure" have only small holes left, the rest of the palate being completely healed.

The Manner of Healing: Effect on the Teeth.

More must be said about the manner of the healing. It has been objected to the flap operation that its method of performance necessarily leads to a large raw surface being left, with such scarring as a result as will generally lead to a short and stiff and functionally imperfect soft palate. In this series, where the hard palate has been operated upon, it has generally shown scarring; in the case of the soft palate this is by no means uniformly the case; several of the patients have well-formed and movable soft palates, with little or no evidence of scarring. This is doubtless due to the device of covering part of the raw surface of the main flap by a second flap derived from the nasal surface of the other half of the soft palate. But in more cases than these the soft palate as well as the hard is scarred, shortened, and its mobility is interfered with.

A result of scarring in the hard palate is sometimes seen in interference with the teeth. It is to be expected that in the case of wide complete clefts—when the flap has been taken not only from the palate but also from the alveolar process—damage might result to the underlying teeth, which are not, of course, protected by bone below. Examination of the cases in this series in which it is most likely that the flap may have been so formed—i.e., children with complete clefts operated upon at or under the age of 6 months—shows that in the majority the temporary teeth are very faulty. In one case (No. 30), seen at the age of 6 years, there were no upper teeth present; while in another (No. 27), at the age of 6½ years, the only teeth present were two incisors in the still much displaced premaxilla, and the two first permanent molars, which were healthy. In most of the cases the teeth showed caries, variable in degree, but in a few they were good.

The permanent teeth apparently escape damage; in many of the cases the first permanent molars were found healthy, and several of the children were old enough to show other healthy permanent teeth. Case 4 is a good example. This boy had a complete cleft palate with left harelip; his first operation was at the age of 3 months. Seen when 6 years old, he possessed in his upper jaw only the two sound first permanent molars and a displaced central incisor; seen again at the age of 10, three other permanent teeth had appeared; these were all sound. (Fig. 1.)

The teeth may be affected in another way, even when the alveolar process has not been encroached upon in making the flap. If much scarring occurs

in the healing of the hard palate the contracting scar tissue may draw inwards one or more of the teeth. Such scarring is of course most likely to occur on the side from which the flap has been raised, since a raw surface is left here; but on the opposite side also, if any extensive raising of the mucoperiosteum from the bone has been done, cicatrization and consequent displacement of the teeth may also occur. The condition may therefore follow Langenbeck's operation, as has been shown by Berry. Several instances were found in the series of cases under discussion.

Fig. 2 shows an extreme case; it represents the palate of a girl, aged 15 (Case 59), who had been operated on at the age of 7 for a cleft of the soft and the posterior three-fourths of the hard palate. Much scarring of the hard palate resulted, with displacement inwards of five of the teeth; the soft palate is short on the left side, but moves fairly. The patient speaks badly, probably owing in part to the condition of the teeth.

The next drawing (Fig. 3) shows displacement inwards of a second bicuspid tooth. The patient, a boy aged 12, had had a cleft of the soft and the posterior fourth of the hard palate operated upon at the age of 2 years and 8 months. The posterior part of the hard palate is scarred, and opposite the displaced tooth there remains a tiny hole. The soft palate, apart from a cleft uvula, is good, and the child spoke fairly, though with a distinctly nasal intonation.

Case 73, shown in Fig. 4, had had two operations, respectively at 13 months and 5½ years, for a cleft involving the soft and the posterior two-thirds of the hard palate. A small hole remains in the hard palate, with scarring around, and the left side of the alveolar arch is pulled inwards. The soft palate is short and moves little; the speech is poor.

A similar flattening of the alveolar arch on the right side is shown by Case 69 (Fig. 5). The cleft, operated upon at the age of 10 months, had been complete, but without harelip. Several teeth on the right side are displaced inwards; the palate is healed, but the soft palate is short and moves very moderately. Speech is fairly good, though nasal.

Condition of Speech.

In considering the effect of the treatment upon the speech account has again only been taken of the results in the 40 patients who have been seen. None of the patients received skilled training after the operation; and the expression of the results is of course to a considerable extent a matter of individual opinion. In tabulating them the cases have been classified according to the extent of the cleft, and the speech has been recorded as either (1) good, (2) fair, or (3) poor or bad.

(a) In 15 cases of complete cleft of hard and soft palate—

The speech was good in	...	1 case.
" " fair in	...	3 cases.
" " poor or bad in	...	11 "

In only 3 of these last 11 cases was the palate completely healed, and 9 of them, including these 3, had undergone more than one operation.

(b) In 19 cases of cleft of soft and part of hard palate—

The speech was good in	...	2 cases.
" " fair in	...	4 "
" " poor or bad in	...	13 "

Only 4 of the 13 "bad" cases had the palate completely healed, and 7 had undergone more than one operation.

(c) In 6 cases of cleft of soft palate only—

The speech was good in	...	3 cases.
" " fair in	...	1 case.
" " poor or bad in	...	2 cases.

Of the 3 cases who spoke well 2 had obtained complete healing after only one operation, and in the third case only a tiny hole remained.

All of these had well-formed and movable soft palates. Fig. 6 represents the palate of Case 8, 9½ years after operation; there is no scarring, and the soft palate, even to the

TABLE III.—100 Consecutive Cases of Cleft Palate treated by Arbuthnot Lane's Operation, with their Immediate and Remote Results.

No.	Sex and age.	Extent of cleft.	Operations.	Immediate result.	Ultimate result.		Last report.
					Palate, &c.	Speech.	
1	M., 7 mos.	Soft palate.	April 25th, 1905.	Complete closure.	Well-formed and freely movable soft palate.	Good. Trouble with <i>th</i> and <i>s</i> . No special training.	Seen Sept., 1911. (Recently dead.)
2	M., 3 mos.	Not stated.	April 25th, 1905.	Not stated.	Cannot be traced.		—
3	M., 7 days.	Complete; right harelip.	1. April 28th, 1905. 2. July 21st, 1905. 3. May 8th, 1906. 4. June, 1907 (lip only). 5. Dec. 10th, 1907.	Partial closure.	Hard palate healed; surface very irregular, especially on right side, owing to scarring. Soft palate almost absent; remnants seen on each side are slightly movable.	Poor; ordinary speech usually unintelligible, but separate words can be understood. Most trouble with <i>b</i> , <i>d</i> , <i>s</i> , <i>th</i> , <i>z</i> , <i>g</i> .	Seen July, 1911.
4	M., 3 mos.	Complete; left harelip.	1. May 2nd, 1905. 2. Jan. 11th, 1907. 3. , 1907 (lip only).	—	Palate healed; arch almost absent. Soft palate moderately movable; uvula absent. Teeth: Only five present in upper jaw; these are sound. (Fig. 1)	Fair; intelligible if he talks slowly. Trouble with <i>s</i> , <i>r</i> .	Seen Dec., 1914.
5	F., 8 wks.	Complete; left harelip.	1. May 19th, 1905. 2. Oct. 24th, 1905.	Small hole left. Hole closed.	Hard palate healed; a carious milk tooth is displaced inwards on to left side of palate. Soft palate: Only most anterior part is joined.	Bad; usually unintelligible and very nasal. Special trouble with <i>b</i> , <i>d</i> , <i>th</i> , hard <i>g</i> , <i>s</i> .	Seen Feb., 1912.
6	F., 2 mos.	Soft, and most of hard palate.	1. May 19th, 1905. 2. Oct. 24th, 1905. 3. Mar., 1906. 4. Jan. 25th, 1907.	—	Hard palate healed, but very lumpy and scarred. Soft palate short, uvula to left; moves very little.	Fair; usually quite intelligible, though nasal. Has been carefully trained by parents.	Seen Sept., 1912.
7	M., 7 yrs.	Not stated.	May 19th, 1905.	Not stated.	Cannot be traced.		—
8	M., 7 mos.	Soft palate.	June 6th, 1905.	Complete closure.	Well formed, moderately movable soft palate. (Fig. 6.)	Very good, almost perfect. No special training.	Seen Jan., 1915.
9	M., 6 wks.	Cleft palate and harelip.	June 16th, 1905.	—	Death June 18th, 1905.		—
10	F., 3 mos.	Soft, and a small part of hard palate.	June 16th, 1905.	Not stated.	Healed; not much scarring. Soft palate moves badly.	Poor; very nasal.	Seen Jan., 1915.
11	F., 5½ mos.	Soft palate.	June 20th, 1905.	Not stated.	Hole, admitting a probe, at junction of soft and hard palates, in middle line. Soft palate movable; its posterior border is oblique, so that palate is short on right side.	Intelligible with difficulty; special trouble with <i>j</i> , <i>th</i> , <i>s</i> , <i>z</i> , <i>r</i> , <i>sc</i> .	Seen Sept., 1911.
12	M., 8 mos.	Hard and soft.	1. June 23rd, 1905. 2. Nov. 17th, 1905. 3. Nov. 23rd, 1906.	Part of soft palate healed. Held well.	"There is a hole in front part of palate. Teeth in upper jaw are rotten."	"Bad. Has had no special training."	Letter from father Sept., 1911.
13	M., 6 yrs.	Soft, and half of hard palate.	1. July 7th, 1905. 2. May 1st, 1906	Small hole left.	Healed; soft palate moderately movable; its posterior border is oblique, making the palate very short on right side. Uvula drawn to right.	Poor; many words quite unintelligible, though many are fairly pronounced; worst trouble with <i>p</i> , <i>b</i> , <i>t</i> , <i>d</i> , <i>k</i> , <i>g</i> . Intelligent boy.	Seen Sept., 1911.
14	M., 10 mos.	Complete; double harelip.	July 7th, 1905. Lip closed Jan., 1906.	Complete closure.	"Palate healed, though narrower than ordinary. Teeth good."	"His teacher can understand, as can home folk, strangers not. Has not had special training."	Letter from father Oct. 23rd, 1911.
15	M., 9 mos.	Complete; right harelip.	July 7th, 1905. Lip closed July 19th, 1905.	Complete closure.	Cannot be traced.		—
16	F., 1½ yrs.	Not stated.	July 11th, 1905.	Not stated.	Cannot be traced.		—
17	F., 9 mos.	Soft palate.	July 18th, 1905.	Complete closure.	Soft palate well-formed—good uvula. Tiny hole on right side at junction of hard and soft palates.	Good; trouble with <i>r</i> . No special training.	Seen Sept., 1911.
18	M., 11 wks.	Complete; left harelip.	July 25th, 1905.	Not stated.	Cannot be traced.		—
19	F., 10 mos.	Soft palate.	July 28th, 1905.	Palate healed.	Death Aug. 24th, 1905. Child wasted continuously after operation—was much worse than before.		Conversation with woman who nursed the child in its illness. Mother seen Sept., 1911.
20	F., 2 mos.	Soft, and posterior two-thirds of hard palate.	1. , 1905. 2. Dec. 1st, 1905.	—	Incomplete closure. Another operation would have been performed, but child died on Good Friday, 1906, after an acute illness of 4 days' duration.		—
21	F., 4 yrs.	Soft, and posterior two-thirds of hard palate.	1. Sept. 1st, 1905. 2. ? date. 3. Oct. 7th, 1906. 4. Jan. 25th, 1907.	Failure. Failure. Partial closure. Collapse and vomiting after operation.	Cannot be traced.		—
22	F., 5 wks.	Soft palate.	Oct., 1905.	Complete closure.	Soft palate healed, not movable. Well-formed uvula.	Poor, scarcely intelligible; special trouble with <i>t</i> , <i>th</i> , <i>r</i> , <i>l</i> .	Seen Sept., 1911.
23	M., 4 mos.	Complete; double harelip.	1. Oct. 16th, 1905. 2. Jan. 30th, 1906.	Anterior part closed. Complete closure.	Cannot be traced.		—
24	F., 11 mos.	Soft, and posterior ½ inch of hard palate.	Oct. 6th, 1905.	Complete closure.	Cannot be traced.		—
25	F., 9 mos.	Soft, and posterior half of hard palate.	Oct. 12th, 1905.	Posterior quarter only healed.	Child died in hospital Jan. 3rd, 1906. Was ill continuously from time of operation until death.		Father seen June, 1912.
26	F., 18 mos.	Soft, and posterior two-thirds of hard palate.	Oct. 26th, 1905.	Palate held.	Death took place a few days after leaving hospital.		Letter from mother Nov., 1911.

TABLE III.—100 Consecutive Cases of Cleft Palate treated by Arbutnot Lane's Operation, with their Immediate and Remote Results—(Continued).

No.	Sex and age.	Extent of cleft.	Operations.	Immediate result.	Ultimate result.		Last report.
					Palate, &c.	Speech.	
27	M., 6 mos.	Complete; double harelip.	1. Oct. 26th, 1905. 2. Feb. 9th, 1906. 3. June 5th, 1906 (lip only).	Anterior half closed. Complete closure.	Premaxilla projects forwards; large gap between it and front of palate, which is closed except median part of anterior half of hard palate. Soft palate closed, but scarred and short. Teeth absent except two incisors and first permanent molars.	Poor; ordinary speech unintelligible, but some isolated words moderately pronounced.	Seen Nov., 1911.
28	F., 3 mos.	Soft, and posterior two-thirds of hard palate.	1. Oct. 31st, 1905. 2. Jan. 30th, 1906. 3. April 13th, 1906. 4. Dec. 17th, 1906.	— — — Failure.	Operations completely failed; practically no palate left except nodular scar tissue at sides of a huge cleft.	Child very nervous; could only be got to say a few words—these almost unintelligible.	Seen Oct., 1911.
29	M., 2½ yrs.	Soft, and posterior quarter of hard palate.	Oct. 31st, 1905.	Complete closure.	Palate healed, except uvula and small hole in hard palate. Soft palate moves fairly. (Fig. 3.)	Fair; distinctly nasal.	Seen Jan., 1915.
30	M., 8 wks.	Complete; double harelip.	1. Nov. 3rd, 1905. 2. Dec. 18th, 1905 (lip only). 3. Mar. 2nd, 1906. 4. May 1st, 1906. 5. Nov. 9th, 1906. 6. July 2nd, 1907. 7. Jan. 14th, 1908.	—	Soft palate absent; hard palate shows a hole, 5 × 4 mm., at anterior part; rest healed, with much nodular scarring. No teeth in upper jaw.	Very bad; generally unintelligible.	Seen Sept., 1911.
31	M., 5 wks.	Soft, and posterior half of hard palate; right incomplete harelip.	Nov. 7th, 1905.	Complete closure.	Death from diarrhoea at age of 11 months.		Letter from father June, 1912.
32	F., 18 mos.	Soft, and posterior half of hard palate.	1. Nov. 14th, 1905. 2. Mar. 7th, 1906. 3. Nov. 23rd, 1906.	Failure. Abscess in neck followed. — Healed.	"Palate is completely closed back and front, but a small hole about middle, which is smaller now than at first."	"Cannot be understood by strangers quite at first, but some are able, and at school she is understood; had no special training. Can read aloud quite plain."	Letter from mother Oct. 23rd, 1911.
33	F., 3 mos.	Soft, and posterior half of hard palate; double harelip.	1. Nov. 21st, 1905. 2. Jan. 26th, 1906.	Partial closure. —	Child died 3 days after return from hospital from pneumonia.		Letter from mother, Oct., 1911.
34	M., 1 mo.	Complete; double harelip.	1. Nov. 21st, 1905.	Anterior two-thirds of cleft closed. Not stated.	Cannot be traced.		—
35	F., 6 wks.	Soft palate.	1. Dec. 1st, 1905. 2. Jan. 23rd, 1906.	Failure. Failure. Very ill with diarrhoea after operation.	Child died, Feb. 22nd, 1906, "in a fit."		Interview with mother Dec., 1914.
36	F., 5 mos.	Congenital central cleft.	Dec. 13th, 1905.	Complete closure.	Child died May, 1908, from "epilepsy and paralysis." Palate was healed.		Letter from father from Canada, Jan., 1912. Seen Oct., 1911.
